routines, to adjust the size of the AUTOKNOB according to how much of the data can be seen. This is also used to decide how far to advance the Pots when User hits the Container of the Gadget. For instance, if you were controlling the display of a 5-line Mindow of text with this Gadget, and there was a total of 15 lines that could be displayed, you would set the VertBody value to (MAXBODY / (TotalLines / DisplayLines)) = MAXBODY / 3. Therefore, the AUTOKNOB would fill 1/3 of the container, and if User hits the Cotainer outside of the knob, the pot would advance 1/3 (plus or minus) If there's no body to show, or the total amount of displayable info is less than the display area, set the Body variables to the MAX. To adjust these after the Cadget is ; these are the variables that intuition sets and maintains WARD pi\_CWidth ; Container width (with any relativity absoluted) WARD pi\_CHeight ; Container height (with any relativity absoluted) ; this flag sez: gimme that old auto-knob ; if set, the knob can move horizontally FREEVERT equ \$0004 ; if set, the knob can move vertically PROPBORDERLESS equ \$0008 ; if set, no border will be rendered KNOEHIT equ \$0100 ; set when this Knob is hit ; minimum vertical size of the knob ; minimum horizontal size of the knob ; added to the System, use ModifyProp(). for every plane of the RastPort, you need define data only for planes that are not entirely zero or one. As you define your Imagery, you will often find that most of the planes ARE just as color selectors. For instance, if you're designing a two-color Gadget to use colors two and three, and the Gadget will reside in a five-plane display, plane zero of your imagery would be all ones, bit plane one would have data that describes the imagery, and bit planes two through four would be

extern APTR AllocMem();
×
   NAME
      CreateStdIO() -- create a standard IO request
   SYNOPSIS
      ioStdReq = CreateStdIO(ioReplyPort);
   FUNCTION
      Allocates memory for and initializes a new IO request block.
   INPUTS
      ioReplyPort - a pointer to an already initialized
             message port to be used for this IO request's
             reply port.
   RESULT
      Returns a pointer to the new block. Pointer is of the type:
      struct IOStdReg
      0 indicates inability to allocate enough memory for either
      the request block.
   EXAMPLE
      struct IOStdReq *myBlock;
      if( (myBlock = CreateStdIO(myPort)) == NULL)
             printf("Insufficient memory or not enough signals!");
   SEE ALSO
      DeleteStdI0
*******************
struct IOStdReq *CreateStdIO(ioReplyPort)
   struct MsgPort *ioReplyPort;
{
   struct IOStdReq *ioStdReq;
```

```
if (ioReplyPort == 0)
       return ((struct IOStdReq

   ioStdReq = AllocMem (sizeof (*ioStdReq), MEMF_CLEAR | MEMF_PUBLIC);
   if (ioStdReq == 0)
       return ((struct IOStdReq *) 0);
   ioStdReq -> io_Message.mn_Node.ln_Type = NT_MESSAGE;
   ioStdReq -> io_Message.mn_Node.ln_Pri = 0;
   ioStdReq -> io_Message.mn_ReplyPort = ioReplyPort;
   return (ioStdReq);
}
NAME
       DeleteStdIO(ioStdReq) - return memory allocated for IO request
   SYNOPSIS
       DeleteStdIO(ioStdReq);
   FUNCTION
       See summary line at NAME. Also frees the signal bit which
       had been allocated by the call to CreateStdIO.
   INPUTS
       A pointer to the IOStdReq block whose resources are to be freed.
   RESULT
       Frees the memory. Returns (no error conditions shown)
   EXAMPLE
       struct IOStdReq *myBlock;
       DeleteStdIO(myBlock);
   SEE ALSO
       CreateStdI0
*********************
DeleteStdIO(ioStdReq)

extern APTR AllocMem();
*
   NAME
*
      CreateExtIO() -- create an Extended IO request
*
   SYNOPSIS
      ioReq = CreateExtIO(ioReplyPort, size);
*
   FUNCTION
      Allocates memory for and initializes a new IO request block
      of a user-specified number of bytes.
   INPUTS
      ioReplyPort - a pointer to an already initialized
             message port to be used for this IO request's reply port.
   RESULT
      Returns a pointer to the new block. Pointer is of the type
      struct IORequest.
      0 indicates inability to allocate enough memory for the request block
      or not enough signals available.
   EXAMPLE
      struct IORequest *myBlock;
      if( (myBlock = CreateExtIO(myPort, sizeof(struct IOExtTD)) == NULL)
             exit(NO_MEM_OR_SIGNALS);
      example used to allocate space for IOExtTD (trackdisk driver
      IO Request block for extended IO operations).
   SEE ALSO

### INTRODUCTION

This section outlines the routines available in the debug.lib.

The debug.lib is a linked-library rather than a shared library. You link to it at compile/link time rather than opening a library. This link-library becomes a physical part of your program code.

Routines that are described in the ROM Kernel manual as well as those listed here, can be called directly from tasks. Routines that are listed in the Lattice C manual, such as printf, and scanf for example, should only be called from a process, rather than from a task in that they require a process model in order to function. A process is started when you ask AmigaDOS to run your program. Any part of main() or any routines it calls become part of that process. If your program spawns any tasks on its own, to have those tasks execute any process-dependent code, the tasks should either send messages back to the main program, which in turn executes the appropriate code, or use these debug routines if the programmer has connected a 9600 baud device to the Amiga's serial port.

To start the debug mode correctly, you can set the serial port parameters by calling

romwack

from a CLI. Then, from the external terminal, type

go

The port is now set up and ready to go. The debug print and get-character routines will function as described below.

debug.lib/KDoFmt

debug.lib/KDoFmt

NAME

KDoFmt -- format data into a character stream.

SYNOPSIS

KDoFmt (FormatString, DataStream, PutChProc, PutChData);
A0 A1 A2 A3

**FUNCTION** 

perform "C"-language-like formatting of a data stream, outputting the result a character at a time

**INPUTS** 

FormatString - a "C"-language-like null terminated format string, with the following supported % types:

DataStream - a stream of data that is interpreted according to the format string.

PutChProc - the procedure to call with each character to be output, called as:

PutChProc (Char, PutChData); D0-0:8 A3

the procedure is called with a null Char at the end of the format string.

PutChData - an address register that passes thru to PutChProc.

```

NAME

SYNOPSIS

KPutStr (string) A0

**FUNCTION** 

put a null terminated string to the debug-console device.

### Appendix G

### **AmigaDOS Topics**

The Amiga ROM Kernel Manual has become somewhat more that just a document covering the ROM Kernel. The name has been kept for historical reasons even though, as of this writing, the "ROM" software loads into kickstart RAM.

Certain topics were not available as of the most recent revision of the AmigaDOS manuals and are, therefore, included here to assure that Amiga developers will have the latest available information on these topics.

These DOS-related topics, which are additional information for the AmigaDOS Technical Reference Manual, are outlined on the following pages.

# Dec 16 13:34 1985 Tech.Ref.Ch4.Sec.1 Page 1

## Chapter 4: AmigaDOS General Information

This chapter describes certain topics which are likely to be of interest to the advanced developer who may wish to create new devices to be added to the Amiga or who wish their code to run with Amiga computers which have been expanded beyond a 512k memory size.

The following topics are covered here:

Overlay Hunk Description

for developers putting together large programs

ATOM utility

works on a new binary file format to change allow developer to set the appropriate load bits.
Assures that program code and data that must be readdent in CHIP memory (the lowest 512k of the system) for the program to function will indeed be placed there by AmigaDOS when it is loaded. Otherwise the program code may not work on an extended memory machine.

Linking in a new DISK-device to AmigaDOS lets a developer add a hard-disk or disk-like device as a name-addressable part of the filing system

Linking in a new non-disk-device to AmigaDOS
lets a developer add such things as additional
serial ports, parallel ports, graphics tablets,
ram-disks or what-have-you to AmigaDOS
(non filing system related).

Using AmigaDOS without using Intuition for developers who may prefer to install and use their own screen handling in place of that provided by Intuition.

## HUNK OVERLAY TABLE - OVERVIEW

When overlays are used, the linker basically produces one very large file containing all of the object modules as hunks of relocatable code. The hunk overlay table contains a data structure that describes the hunks and their relationship to each other.

When you are designing a program to use overlays, you must keep in mind how the overlay manager (also called the overlay supervisor) handles the interaction between the various segments of the file. What you must do, basically, is build a tree that reflects the relationships between the various code modules that are a part of the overall program and tell the linker how this tree should be constructed.

The hunk overlay table is generated as a sets of 8 longwords, each describing a particular overlay node that is part of the overall file. Each 8 longword entry is comprised of the following data:

# HUNK OVERLAY SYMBOL TABLE-ENTRY DATA STRUCTURE:

long seekOffset; /\* where in the file to find this node \*/
long dwmmy;
/\* a value of 0 ... compatibility item \*/
long dwmmy;
/\* a value of 0 ... compatibility item \*/
long dwmmy;
/\* a value of 0 ... compatibility item \*/
long dwmmy;
/\* item number at that level \*/
long firstHunk; /\* hunk number of the first hunk containing
\* this node. \*/
long symbolikunk; /\* the hunk number in which this symbol is
\* located \*/
long symboloffsetX; /\* (offset \* 4), where offset is the offset
\* within the symbol hunk at which this
\* symbol's entry is located. \*/

Each of these items is explained further in the sections that follow.

### DESIGNING AN OVERLAY TREE

If you have, for example, the files: main, a, b, c, d, e, f, g, h, i and j. Lets say that main can call a,b,c, and d and that each of these files can call main. Additionally lets say that routine e can be called from a,b,c,d or main, but has no relationship to routine f. Thus, if a routine in e is to be run, then a,b,c, and d need to be memory resident as well. Routine f is like e; that is, it needs nothing in e to be present, but can be called from a, b, c, or d. This means that the overlay manager can share the memory espace between routines e and f, since neither need ever be memory coresident with the other in order to run.

If you consider routine g to share the same space as the combination of a,b,c, and d and routines h,i and j sharing the same space, you have the basis for constructing the overlay tree for this program structure:

Not only have we drawn the tree, but we have labeled its branches to match the hunk overlay (level, ordinate) numbers that are found in the hunk overlay table that matches the nodes to which they are assigned.

From the description above, you can see that if main is to call any routine in program segment a-d, then all of those segments should be resident in memory at the same time. Thus they have all been assigned to a single node by the linker. While a-d are resident, if you call routines in e, the linker will automatically load routine e from disk, and reinitialize the module (each time it is again brought in), so that its subroutines will be available to be run. If any segment a-d calls a routine in f, the linker replaces e with the contents of f and initializes it.

Thus a-d are at level 1 in the overlay tree, and routines e and f are at level 2, requiring that a-d be loaded before e or f can be accessed and loaded for execution.

NOTE: A routine can only perform calls to routines in other nodes which either are currently memory resident (the ancestors of the node in which the routine now in use is located), or a routine in a direct child node. That is, main cannot call e directly, but e can call routines in main since main is an ancestor.

Note also that within each branch of each subnode, for a given level, the ordinate numbers begin again with number 1.

### DESCRIBING THE TREE

You create the tree by telling the overlay linker about its structure. The numerical values, similar to those noted in the figure above, are assigned sequentially by the linker itself and appear in the hunk node table. Here is the sequence of overlay link statements that cause the figure above to be built:

OVERLAY a,b,c,d

•

o.€

Dec 16 13:34 1985 Tech.Ref.Ch4.Sec.1 Page 3

This description tells the linker that a,b,c,d are part of a single node at a given level (in this case level 1), and the asterisk in front of e and f each say that these are one each on the next level down from a-d, and accessible only through a-d or anything closer towards the root of the tree. The name g has no asterisk, so it is considered on the same level as a-d, telling the linker that either a-d or g will be memory resident, but

The above paragraphs have explained the origin of the hunk node level and the hunk ordinate in the hunk overlay symbol-table.

### SEEK OFFSET AMOUNT

The first value for each node in the overlay table is the seek offset. As specified earlier, the overlay linker builds a large single file containing all of the overlay nodes. The seek offset number is that value that can be given to the seek(file, byte\_offset) routine to point to the first byte of the hunk header of a node.

### INITIALHUNK

The initialHunk value in the overlay symbol-table is used by the overlay manager when unloading a node. It specifies the initial hunk that must have been loaded in order to have loaded the node that contains this symbol. When a routine is called at a different level and ordinate, (unless it is a direct, next level, child of the current node, it will become necessary to free the memory utilized by invalid hunks, so as to make room to overlay with the hunk(s) containing the desired symbol.

## SYMBOLHUNK AND SYMBOLOFFSETX

These table entries for the symbols are used by the overlay manager to actually locate the entry point once it has either determined it is already loaded or has loaded it. The symbolHunk shows in which hunk to locate the symbol. SymbolOffsetX-4 shows the offset from the start of that hunk at which the entry point is actually located.

(Alink Temporary Object Modifier) ---- ATOM: ----

This document describes the ATOM utility, including its development history, the manner in which it has been implemented, and alternatives to its use.

The "problem":

Programmers need/want to be able to specify that parts of their program go into "chip" memory (the first 512k) so that the custom chips can access it. They also need/want to treat this data just like any other data in their program and therefore have it link and load normally.

Previous solutions:

The recommended way of dealing with this was to do an Allochem with the chip memory bit set and copy data from where it was loaded ("fast" memory) to where it belonged (chip memory), then use pointers to get to it. This involved having two copies of your data in memory, the first loaded with your program, the second copied into the first 512k of memory. The other "solution" is to have the program not run in machines with more than 512k. This should quickly become an unacceptable solution.

The ATOM solution:

1) Compile or assemble normally

- 2) Pass the object code through a post (or pre) processor called "AIOM". AIOM will interact with the user and the object file(s). It will flag the desired hunks (or all hunks) as "for chip memory" by changing the hunk type.
- The old types were hunk code, hunk data, and hunk bas. linker will now take nine (9) hunk types instead of 3. hunk\_code\_chip ones will be: Dev 8 ଳ

= hunk\_code + bit 30 set = hunk\_code + bit 31 set = hunk\_data + bit 30 set = hunk\_data + bit 31 set = hunk\_bss + bit 30 set = hunk\_bss + bit 31 set hunk code fast hunk\_data\_chip hunk\_data\_fast hunk\_bss\_chip hunk bss\_fast

The linker will pass all hunk types through to the LOADER, (coagulating if necessary). The LOADER uses the hunk

Dec 16 13:36 1985 Tech.Ref.Ch4.Sec.2 Page 2

header information when loading.

and BSS hunks contained uninitialized linker documentation that CODE hunks contain executable (68000) machine language, DATA hunks contain initialized (ou will recall from the information provided in the data (arrays, variable declorations, ...). (constants, ...) data

- above. Hunks will go into the designated memory type. 4) The LOADER will load according to information from step 3)
- 5) Old versions of the LOADER will interpret the new hunk types as VERY large hunk and not load (error 103, not enough memory).

Future Solutions:

The assembler and Lattice "C" may be changed to generate the new hunk types under programmer control.

How the bits work:

address space machines, the upper 2 bits are unused. The Bits The hunk size is a word containing the number of words in the hunk. Therefore for the foreseeable future including 32 bit have been redefined as follows:

MEME\_EAST MEME\_CHIP +-- B1t30 B1t31 -----+

If neither bit is set then get whatever memory is available, this is "backwards" compatible.
Preference is given to "Fast" memory.
Loader must get FAST memory, or fail.
Inder must get CHIP memory, or fail.
If Bit31 and Bit30 are both set then there is

extra information available following this long word. This is reserved for future expansion, as needed. It is not currently used.

Perceived impact:

extended memory, if poorly programmed. The "previous solutions" mentioned at the beginning of this chapter still hold. run through Old programs, programs that have not been compiled of assembled with the new options, and programs that have not been ATCH will run (or not) as well as ever. This includes

EXACILY the same loop you have now... edit, compile, link, execute, test, edit,... UNTIL you are about to release. Then you edit, compile, ATOM, Alink, add external memory (>512k) and test. This works well for all three environments (Amiga, IBM and Program development and test on a 512k machine could follow

Dec 16 13:36 1985 Tech.Ref.Ch4.Sec.2 Page 3

For native (Amiga) development on a >512k machine you may want to ATCM the few required object files so you can both run your linked program in an extended memory machine and take advantage of a large RAM: disk. The development cycle then becomes: edit, compile, optionally ATCM (if this code or data contains items needed by the blitter), link, extente, test, edit...

"New programs" will not load in a VI.0 Kickstart environment. The result will be error 103, not enough memory.

Old (V1.0 and before) versions of dumpobj and OMD will not work on files after ATOM has been run on them.

Working Environment:

To get all of this to work together you need Release 1.1 compatible coples of:

AIOM (Version 1.0 or later)

Alink (Version 3.30 or later) Kickstart (Release 1.1 or later) for DOS LOADER. DumpObj (Version 2.1) Needed If you wish to examine programs modified by ATCH

AICM Command Line Syntax:

The command line syntax is:

ATCM <infile> <outfile> [-I]

ATON (Infiles (-C[C[D[B]] [-F[C[D[B]] [-P[C[D[B]]

Where: <infile>

(Any type of memory Represents an object file, just compiled, assembled or ATCMed (Yes you can re-ATCM The destination for the converted file. Change memory to CHIP Change memory to FAST Change memory to "Public". Change CODE hunks Change DATA hunks Change BSS hunks an object file. available.) coutfile> ረ ት ት

Command Line Examples:

Example #1 In most cases there is no need to place CODE hunks in chip memory. Sometimes DATA and BSS hunks do need to

## Dec 16 13:36 1985 Tech.Ref.Ch4.Sec.2 Page 4

be placed in chip memory, therefore the fillowing is a fairly common usage of ATCM. To cause all Code hunks go into Public RAM, Data and BSS hunks to go into chip

ATOM infile.obj outfile.obj -pc -cdb

Example #2 To cause all the hunks in object file to be loaded into chip memory type: ATCM infile.obj outfile.obj

To set all data hunks to load into chip memory type: atom myfile.o myfile.set.o -cd Example #3

Example #4
This is an interactive example. User input is in lower computer output is in upper case. In this example the code hunk is set to "Fast", the data hunk is set to "Chip". There were no BSS hunks. Note that help was requested in the beginning.

Making New Disk Devices

To create a new disk device, you must construct a new device node as described in section 3.3.1 of the AmigaDos Technical manual. You must also write a device driver for the new disk device.

performed by the trackdisk device (described in the Amiga ROM Kernel manual). It must include the ability to respond to commands such as read, write, seek, and return status information in the same way as described for the trackdisk driver. A device driver for a new disk device must mimic the calls that are

For the following description, note that most pointers are of the type HPTR (as described in the AmigaDOS Technical Reference Manual), a machine pointer to some longword-aligned memory location(such as returned by AllocMem), shifted right by two.

Construct the new node with the following fields:

Global vector dt\_device Task Stacksize Priority Handler Next Š BPTR to startup info BSTR to name Seglist

The BSTR to a name is a BCPL pointer to the name of your new device (such as HD0:) represented as the length of the string in the first byte, and the characters following.

The Seglist must be the segment list of the filling system task. To obtain this, you must access a field in the process base of one of the filling system tasks.

The code as follows can be used for this purpose:

UBYTE \*port;

port = DeviceProc( "DF0:"); /\* Returns msg port of filesystem task \*/
task = (struct Task \*) (port-sizeof(struct Task);

/\*Task structure is below port \*/
list = ( task.pr\_Seglist ) << 2; /\* make machine ptr from SegArray
segl = list[3]; /\* Third element in SegArray is filesystem seglist</pre>

Next, you must set up the startup info (again, remember to use EPTRs where needed). This info consists of a EPTR to three long words which contain:

- Unit number (do not use unit zero) Davice driver name, stored as a RPTR to the device driver name.

Dec 16 13:36 1985 Tech.Ref.Ch4.Sec.3 Page 2

which must be terminated by a null byte which is included in the count (e.g.,  $4/1H^{1/1}D^{1/10}/0$ ) BFTR to disk information

The disk size information contains the following longword fields:

| Size of table | Disk block size in long words<br>(assuming 512-byte blocksize) | Sector origin (1.e., first sector is sector zero) | (e.g., 2 for floppy disk) | Number of sectors per block | (e.g., 11 for floppy disk)    | <pre>(or more, indicating number of blocks to be reserved at start)</pre> | Presllocation factor | Interleave factor | (commonly 0)              | (e.g., 79 for floppy dlak) |
|---------------|----------------------------------------------------------------|---------------------------------------------------|---------------------------|-----------------------------|-------------------------------|---------------------------------------------------------------------------|----------------------|-------------------|---------------------------|----------------------------|
| 11            | 128                                                            | 0                                                 | Number of surfaces        | 1                           | Number of blocks<br>per track | 7                                                                         | •                    | •                 | Lowest cylinder<br>number | Highest cylinder<br>number |

Finally, the device node must be attached to the end of the list (note the Next fleids are all BPTRs) of device nodes within the Info substructure. WaRNING: the list to which this refers is NOT the same kind of list that is referenced in the Exec portion of the Amiga ROM Kernel manual, but is instead the kind of list described in the AmigaDOS Technical Reference Manual.

(or more, indicating number of cache blocks)

To partition a hard disk, you make two or more device nodes and set the lowest and highest cylinder numbers to partition the disk as desired.

Dec 16 13:37 1985 Tech.Ref.Ch4.Sec.4 Page 1

Creating a New Device to Run under AmigaDOS

This section provides information about adding devices that are NOT part of the DOS filling system. The next section provides information about adding file-system-related devices (hard-disks, floppy disks), that is, devices that DOS can use to read and write files with their associated directories.

You would want to use this information to add a new device such as a new serial port or a new parallel port. In this case you may be creating a device named "SER2:" which is to act just like "SER:" as far as DOS is concerned.

There are two steps involved here. First, you must create a suitable device, a process that is not addressed here. Note: The code for creating a skeleton disk-resident device is contained in the Amiga ROM Kernel Manual.

Second, you must make this new device available as an AmigaDOS device. This process involves writing a suitable device handler (see ROM Kernel Manual) and installing it into the AmigaDOS structures.

This installation is handled by creating a suitable device node structure for your new device. This is similar to creating a Devinfo slot for a new disk device, except that the start-up argument can be anything you want, the Segment list slot is zero, and the file name of your disk-resident device handler is placed in the Filename slot.

o dt\_device
1 Task (or process id - see below)
2 Lock
BSTR Filename of handler code
NNN Stacksize required
NN Priority required
XXX Startup information
0 Segiist (nonzero if you load the code)
0 Global vector required
BSTR Device Name

The device handler is the interface between your device and an application program. This is normally written in BCPL, and the AmigaDOS kernel will attempt to load the code of the handler and create a new process for it when it is first referenced. This is handled automatically when the kernel notices that the Task field in the DevInfo structure is zero. If the code is already loaded, the code agament pointer is placed in the SegList field. If this field is zero, the kernel loads the code from the filename given in the Filename field and updates the SegList field.

If you want this automatic loading and process initialization to work, you must create a code module, which is written in BCPL or is written in assembler to look like a BCPL module. This ensures that the dynamic linking used by the loarnel will work correctly.

If you are writing in assembler, the format of the code section must be as shown below. Note that you may use DATA and BSS sections, but

```
LET open = FALSE // flag to show whether device has been "opened"
// with act.findimput or act.findoutput
                                                                                                                                                                                                                                                                                                                                                                                                                                                                              outpkt!pkt.type := act.write
impkt!pkt.type := act.read
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             returnpkt (parm.pkt, TRUE)

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   // Finished with parameter packet...send back...
                                                                                                                                                                                                                                          $ (returnpkt (parm.pkt, FALSE, error, objectinuse)
                                                                                                                                                                                                                                                                                                                                                                                      FOR 1=0 TO IO.blocksize DO IOBO11 := IOB11
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        .....scb.id := TRUE // Interactive

If you wish to write your device handler in C, you cannot use the automatic load and process creation provided by the kernel. In this case, you must load the code yourself and use a call to CreateProc to create a process. The result from this call should be stored in the Task field of

# Dec 16 13:37 1985 Tech.Ref.Ch4.Sec.4 Page 5

the Devinfo structure. You must then send a message to the new process to get it started. This message might contain such things as the unit number of the device involved. The handler process should then wait for Open, Read, Write, and Close calls and handle them as described in the example above. C code does not need to insert the process id into the device node because this is done when code is loaded, as described above.

// Write request returning

Using AmigaDOS Without Workbench/Intuition

This information is provided to give developers some information about how AmigaDOS and intuition interact with each other. As of this writing, it is not possible to fully close down intuition or the input device. It is possible to install one sown input handler within the input stream (as is demonstrated in the Amiga ROW Kernel Manual, Input Device description) and thereby handle input events yourself, after your program has been loaded and started by AmigaDOS. If, after that point, you take over the machine in some manner, you can prevent AmigaDOS from trying to put up system requesters or otherwise interacting with the screen by modifying DOS as shown below. Basically, your own program must provide alternate ways to handle errors that would normally cause DOS to put up a requester.

Another alternative for taking over the machine is to ignore the AmigaDOS filling system altogether, and use the trackdisk device to boot your code and data on your own. You will find defails about the disk boot block and the track formatting in the Amiga ROM Kernel Manual, allowing this alternate means if you so choose.

Here are the details about AmigaDOS and Intuition:

G-9

AmigaDOS initializes itself and opens Intuition. It then attempts to open the configuration file (created by Preferences) and passes this to Intuition. It then opens the initial CLI window via Intuition and attempts to run the first CLI command. This is commonly a loadwb (load Workbench), followed by an endcli on the initial CLI.

An application program can be made to behave like Workbench, in that it spawns off a new process. The next CLI command is then endcli, which closes everything down, leaving only the new process running (along with the filesystem processes). This process would set the pr\_WindowPtr field to -1, which indicates that the DOS should report errors quietly. Note that the application MIST handle all errors. There are further details on this in the AmigaDOS Technical manual, chapter 3. DOS will also have initialized the TrapHandler field of the user task to point to code that will display a requester after an error; this should be replaced by a user-provided routine. This will stop all uses of Intuition from the in which case DOS will call Exec Alert directly.

There is still the problem that the filesystem processes may ask for a requester, in the event of a disk error or if the filesystem task crashes due to memory corruption. To stop this, the pr\_MindowPtr and tc\_TrapHandler fields of the filesystem tasks must be set to -1 and a private Trap handler must be provided in the same way as was done for the user task. This is easily done as shown below.

Find the message port for each filesystem task by calling DeviceProc(), passing DE0, DE1, etc. An error indicates that the device is not present. From the message port you can find the task base for each filesystem task, and hence patch these two slots. This should be repeated for each disk unit.

The application program can now close Intuition. Worldench has, of

Dec 16 13:38 1985 Tech.Ref.Ch4.Sec.5 Page 2

course, never been invoked. Note that as of this writing, it is not possible to stop DOS from opening intuition.

Note that if the application want to use any other device such as SER:, the handler process must be patched in exactly the same way as the file-ystem processes. The application should obviously not attempt to open the CON: or RAW: once Intuition has become inactive.

# Appendix H

# IFF Interchange File Format

This appendix contains a document developed jointly by Commodore-Amiga and Electronic Arts.

The document contained here includes source code for routines that will both read and write this data format.

Commodore-Amiga has adopted this data interchange file format for our internal use and we recommend that our developers adopt it as well.

|  |   | * |
|--|---|---|
|  | • |   |
|  |   |   |

# INFORMATION ABOUT COMPILING THESE ROUTINES:

Electronic arts apparently keeps a bunch of includes in a file called "graphics/system.h".

This is the contents of that include-file:

```
#include exec/types.h
#include exec/exec.h
#include graphics/gfx.h
#include graphics/gfxbase.h
#include graphics/copper.h
#include graphics/regions.h
#include graphics/regions.h
#include hardware/blit.h
#include intuition/intuition.h
#include intuition/intuitionbase.h
#include libraries/dos.h
```

OFFSET\_BEGINNING in iffr.c and iffw.c must be changed to OFFSET\_BEGINING. It is spelled differently in libraries/dos.h.

In Ilbmr.c (p.3) there is a call to UnPackRow:

UnPackRow(&buf, \*pDest, nFilled, srcRowBytes)

nFilled and srcRowBytes are defined as int and LONG. The function expects WORD and WORD. To compile with native Lattice required:

UnPackRow(&buf, \*pDest, (WORD)nFilled, (WORD)srcRowBytes)

# "EA IFF 85" Standard for Interchange Format Files

Document Date:

November 15, 1985

From:

Jerry Morrison, Electronic Arts

Status of Standard:

Released and in use

# 1. Introduction

# Standards are Good for Software Developers

As home computer hardware evolves to better and better media machines, the demand increases for higher quality, more detailed data. Data development gets more expensive, requires more expertise and better tools, and has to be shared across projects. Think about several ports of a product on one CD-ROM with 500M Bytes of common data!

Development tools need standard interchange file formats. Imagine scanning in images of "player" shapes, moving them to a paint program for editing, then incorporating them into a game. Or writing a theme song with a Macintosh score editor and incorporating it into an Amiga game. The data must at times be transformed, clipped, filled out, and moved across machine kinds. Media projects will depend on data transfer from graphic, music, sound effect, animation, and script tools.

# Standards are Good for Software Users

Customers should be able to move their own data between independently developed software products. And they should be able to buy data libraries usable across many such products. The types of data objects to exchange are open-ended and include plain and formatted text, raster and structured graphics, fonts, music, sound effects, musical instrument descriptions, and animation.

The problem with expedient file formats—typically memory dumps—is that they're too provincial. By designing data for one particular use (e.g. a screen snapshot), they preclude future expansion (would you like a full page picture? a multi-page document?). In neglecting the possibility that other programs might read their data, they fail to save contextual information (how many bit planes? what resolution?). Ignoring that other programs might create such files, they're intolerant of extra data (texture palette for a picture editor), missing data (no color map), or minor variations (smaller image). In practice, a filed representation should rarely mirror an in-memory representation. The former should be designed for longevity; the latter to optimize the manipulations of a particular program. The same filed data will be read into different memory formats by different programs.

The IFF philosophy: "A little behind-the-scenes conversion when programs read and write files is far better than NxM explicit conversion utilities for highly specialized formats."

So we need some standardization for data interchange among development tools and products. The more developers that adopt a standard, the better for all of us and our customers.

# Here is "EA IFF 1985"

Here is our offering: Electronic Arts' IFF standard for interchange File Format. The full name is "EA IFF 1985". Alternatives and justifications are included for certain choices. Public domain subroutine packages and utility programs are available to make it easy to write and use IFF-compatible programs.

Part 1 introduces the standard. Part 2 presents its requirements and background. Parts 3, 4, and 5 define the primitive data types, FORMs, and LISTs, respectively, and how to define new high level types. Part 6 specifies the top level file structure. Appendix A is included for quick reference and Appendix B names the committee responsible for this standard.

# 2. Background for Designers

Part 2 is about the background, requirements, and goals for the standard. It's geared for people who want to design new types of IFF objects. People just interested in using the standard may wish to skip this part.

# What Do We Need?

A standard should be long on prescription and short on overhead. It should give lots of rules for designing programs and data files for synergy. But neither the programs nor the files should cost too much more than the expedient variety. While we're looking to a future with CD-ROMs and perpendicular recording, the standard must work well on floppy disks.

For program portability, simplicity, and efficiency, formats should be designed with more than one implementation style in mind. (In practice, pure stream I/O is adequate although random access makes it easier to write files.) It ought to be possible to read one of many objects in a file without scanning all the preceding data. Some programs need to read and play out their data in real time, so we need good compromises between generality and efficiency.

As much as we need standards, they can't hold up product schedules. So we also need a kind of decentralized extensibility where any software developer can define and refine new object types without some "standards authority" in the loop. Developers must be able to extend existing formats in a forward-and backward-compatible way. A central repository for design information and example programs can help us take full advantage of the standard.

For convenience, data formats should heed the restrictions of various processors and environments. E.g. word-alignment greatly helps 68000 access at insignificant cost to 8088 programs.

Other goals include the ability to share common elements over a list of objects and the ability to construct composite objects containing other data objects with structural information like directories.

"Simple things should be simple and complex things should be possible."

# Think Ahead

Let's think ahead and build programs that read and write files for each other and for programs yet to be designed. Build data formats to last for future computers so long as the overhead is acceptable. This extends the usefulness and life of today's programs and data.

To maximize interconnectivity, the standard file structure and the specific object formats must all be general and extensible. Think ahead when designing an object. It should serve many purposes and allow many programs to store and read back all the information they need; even squeeze in custom data. Then a programmer can store the available data and is encouraged to include fixed contextual details. Recipient programs can read the needed parts, skip unrecognized stuff, default missing data, and use the stored context to help transform the data as needed.

# Scope

IFF addresses these needs by defining a standard file structure, some initial data object types, ways to define new types, and rules for accessing these files. We can accomplish a great deal by writing programs according to this standard, but don't expect direct compatibility with existing software. We'll need conversion programs to bridge the gap from the old world.

IFF is geared for computers that readily process information in 8-bit bytes. It assumes a "physical layer" of data storage and transmission that reliably maintains "files" as strings of 8-bit bytes. The standard treats a "file" as a container of data bytes and is independent of how to find a file and whether it has a byte count.

This standard does not by itself implement a dipboard for cutting and pasting data between programs. A dipboard needs software to mediate access, to maintain a "contents version number" so programs can detect updates, and to manage the data in "virtual memory".

## **Previous Work**

Where our needs are similar, we borrow from existing standards.

Our basic need to move data between independently developed programs is similar to that addressed by the Apple Macintosh desk scrap or "clipboard" [Inside Macintosh chapter "Scrap Manager"]. The Scrap Manager works closely with the Resource Manager, a handy filer and swapper for data objects (text strings, dialog window templates, pictures, fonts...) including types yet to be designed [Inside Macintosh chapter "Resource Manager"]. The Resource Manager is a kin to Smalltalk's object swapper.

We will probably write a Macintosh desk accessory that converts IFF files to and from the Macintosh clipboard for quick and easy interchange with programs like MacPaint and Resource Mover.

Macintosh uses a simple and elegant scheme of 4-character "identifiers" to identify resource types, clipboard format types, file types, and file creator programs. Alternatives are unique ID numbers assigned by a central authority or by hierarchical authorities, unique ID numbers generated by algorithm, other fixed length character strings, and variable length strings. Character string identifiers double as readable signposts in data files and programs. The choice of 4 characters is a good tradeoff between storage space, fetch/compare/store time, and name space size. We'll honor Apple's designers by adopting this scheme.

"PICT" is a good example of a standard structured graphics format (including raster images) and its many uses [Inside Macintosh chapter "QuickDraw"]. Macintosh provides QuickDraw routines in ROM to create, manipulate, and display PICTs. Any application can create a PICT by simply asking QuickDraw to record a sequence of drawing commands. Since it's just as easy to ask QuickDraw to render a PICT to a screen or a printer, it's very effective to pass them between programs, say from an illustrator to a word processor. An important feature is the ability to store "comments" in a PICT which QuickDraw will ignore. Actually, it passes them to your optional custom "comment handler".

PostScript, Adobe's print file standard, is a more general way to represent any print image (which is a specification for putting marks on paper) [PostScript Language Manual]. In fact, PostScript is a full-fledged programming language. To interpret a PostScript program is to render a document on a raster output device. The language is defined in layers: a lexical layer of identifiers, constants, and operators; a layer of reverse pollsh semantics including scope rules and a way to define new subroutines; and a printing-specific layer of built-in identifiers and operators for rendering graphic images. It is clearly a powerful (Turing equivalent) image definition language. PICT and a subset of PostScript are candidates for structured graphics standards.

A PostScript document can be printed on any raster output device (including a display) but cannot generally be edited. That's because the original flexibility and constraints have been discarded. Besides, a PostScript program may use arbitrary computation to supply parameters like placement and size to each operator. A QuickDraw PICT, in comparison, is a more restricted format of graphic primitives parameterized by constants. So a PICT can be edited at the level of the primitives, e.g. move or thicken a line. It cannot be edited at the higher level of, say, the bar chart data which generated the picture.

PostScript has another limitation: Not all kinds of data amount to marks on paper. A musical instrument description is one example. PostScript is just not geared for such uses.

"DIF" is another example of data being stored in a general format usable by future programs [DIF Technical Specification]. DIF is a format for spreadsheet data interchange. DIF and PostScript are both expressed in plain ASCII text files. This is very handy for printing, debugging, experimenting, and transmitting across moderns. It can have substantial cost in compaction and read/write work, depending on use. We won't store IFF files this way but we could define an ASCII alternate representation with a converter program.

InterScript is Xerox' standard for interchange of editable documents [Introduction to InterScript]. It approaches a harder problem: How to represent editable word processor documents that may contain formatted text, pictures, cross-references like figure numbers, and even highly specialized objects like mathematical equations? InterScript aims to define one standard representation for each kind of information. Each InterScript-compatible editor is supposed to preserve the objects it doesn't understand and even maintain nested cross-references. So a simple word processor would let you edit the text of a fancy document without discarding the equations or disrupting the equation numbers.

Our task is similarly to store high level information and preserve as much content as practical while moving it between programs. But we need to span a larger universe of data types and cannot expect to centrally define them all. Fortunately, we don't need to make programs preserve information that they don't understand. And for better or worse, we don't have to tackle cross-references yet.

# 3. Primitive Data Types

Atomic components such as integers and characters that are interpretable directly by the CPU are specified in a format most convenient for the Motorola MC68000 processor [M68000 16/32-Bit Microprocessor Programmer's Reference Manual].

N.B.: Part 3 dictates the format for "primitive" data types where—and only where—used in the overall file structure and standard kinds of chunks (Cf. Chunks). The number of such occurrences will be small enough that the costs of conversion, storage, and management of processor-specific files would far exceed the costs of conversion on-the-fly by "foreign" programs. A particular data chunk may be specified with a different format for its internal primitive types or with processor- or environment-specific variants if necessary to optimize local usage. Since that hurts data interchange, it's not recommended. (Cf. Designing New Data Sections, in Part 4.)

# **Alignment**

All data objects larger than a byte are aligned on <u>even</u> byte addresses relative to the start of the file. This may require padding. Pad bytes are to be written as zeros, but don't count on that when reading.

This means that every odd-length "chunk" (see below) <u>must</u> be padded so that the next one will fall on an even boundary. Also, designers of structures to be stored in chunks should include pad fields where needed to align every field larger than a byte. Zeros should be stored in all the pad bytes.

Justification: Even-alignment causes a little extra work for files that are used only on certain processors but allows 68000 programs to construct and scan the data in memory and do block I/O. You just add an occasional pad field to data structures that you're going to block read/write or else stream read/write an extra byte. And the same source code works on all processors. Unspecified alignment, on the other hand, would force 68000 programs to (dis)assemble word and long-word data one byte at a time. Pretty cumbersome in a high level language. And if you don't conditionally compile that out for other processors, you won't gain anything.

# Numbers

Numeric types supported are two's complement binary integers in the format used by the MC68000 processor—high byte first, high word first—the reverse of 8088 and 6502 format. They could potentially include signed and unsigned 8, 16, and 32 bit integers but the standard only uses the following (in C):

# Characters

The following character set is assumed wherever characters are used, e.g. in text strings, IDs, and TEXT chunks (see below).

Characters are encoded in 8-bit ASCII. Characters in the range NUL (hex 0) through DEL (hex 7F) are well defined by the 7-bit ASCII standard. IFF uses the graphic group " " (SP, hex 20) through "~" (hex 7E).

Most of the control character group hex 01 through hex 1F have no standard meaning in IFF. The control character LF (hex 0A) is defined as a "newline" character. It denotes an intentional line break, that is, a

paragraph or line terminator. (There is no way to store an automatic line break. That is strictly a function of the margins in the environment the text is placed.) The control character ESC (hex 1B) is a reserved escape character under the rules of ANSI standard 3.64-1979 <u>American National Standard Additional Control Codes for Use with ASCII</u>, ISO standard 2022, and ISO/DIS standard 6429.2.

Characters in the range hex 7F through hex FF are not globally defined in IFF. They are best left reserved for future standardization. But note that the FORM type FTXT (formatted text) defines the meaning of these characters within FTXT forms. In particular, character values hex 7F through hex 9F are control codes while characters hex A0 through hex FF are extended graphic characters like Å, as per the ISO and ANSI standards cited above. [See the supplementary document "FTXT" IFF Formatted Text.]

# **Dates**

A "creation date" is defined as the date and time a stream of data bytes was created. (Some systems call this a "last modified date".) Editing some data changes its creation date. Moving the data between volumes or machines does not.

The IFF standard date format will be one of those used in MS-DOS, Macintosh, or Amiga DOS (probably a 32-bit unsigned number of seconds since a reference point). Issue: Investigate these three.

# Type IDs

A "type ID", "property name", "FORM type", or any other IFF identifier is a 32-bit value: the concatenation of four ASCII characters in the range "." (SP, hex 20) through "~" (hex 7E). Spaces (hex 20) should not precede printing characters; trailing spaces are ok. Control characters are forbidden.

typedef CHAR ID[4];

IDs are compared using a simple 32-bit case-dependent equality test.

Data section type IDs (aka FORM types) are restriced IDs. (Cf. Data Sections.) Since they may be stored in filename extensions (Cf. Single Purpose Files) lower case letters and punctuation marks are forbidden. Trailing spaces are ok.

Carefully choose those four characters when you pick a new ID. Make them mnemonic so programmers can look at an interchange format file and figure out what kind of data it contains. The name space makes it possible for developers scattered around the globe to generate ID values with minimal collisions so long as they choose specific names like "MUS4" instead of general ones like "TYPE" and "FILE". EA will "register" new FORM type IDs and format descriptions as they're devised, but collisions will be improbable so there will be no pressure on this "clearinghouse" process. Appendix A has a list of currently defined IDs.

Sometimes it's necessary to make data format changes that aren't backward compatible. Since IDs are used to denote data formats in IFF, new IDs are chosen to denote revised formats. Since programs won't read chunks whose IDs they don't recognize (see Chunks, below), the new IDs keep old programs from stumbling over new data. The conventional way to chose a "revision" ID is to increment the last character if it's a digit or else change the last character to a digit. E.g. first and second revisions of the ID "XY" would be "XY1" and "XY2". Revisions of "CMAP" would be "CMA1" and "CMA2".

# Chunks

Chunks are the building blocks in the IFF structure. The form (in C) is

The fixed header part means "Here's another ckID type chunk, ckSize bytes long."

The ckID identifies the format and purpose of the chunk. As a rule, a program must recognize ckID to interpret ckData. It should skip over all unrecognized chunks. The ckID also serves as a format version number as long as we pick new IDs to identify new formats of ckData (see above).

The following ckIDs are universally reserved to identify chunks with particular IFF meanings: "LIST", "FORM", "PROP", "CAT", and " ". The special ID " " (4 spaces) is a ckID for "filler" chunks, that is, chunks that fill space but have no meaningful contents. The IDs "LIS1" through "LIS9", "FOR1" through "FOR9", and "CAT1" through "CAT9" are reserved for future "version number" variations. All IFF-compatible software must account for these 23 chunk IDs. Appendix A has a list of predefined IDs.

The cksize is a logical block size—how many data bytes are in ckData. If ckData is an odd number of bytes long, a 0 pad byte follows which is <u>not</u> included in cksize. (Cf. Alignment.) A chunk's total physical size is cksize rounded up to an even number plus the size of the header. So the smallest chunk is 8 bytes long with cksize = 0. For the sake of following chunks, programs must respect every chunk's cksize as a virtual end-of-file for reading its ckData even if that data is malformed, e.g. if nested contents are truncated.

We can describe the syntax of a chunk as a regular expression with "#" representing the cksize, i.e. the length of the following {braced} bytes. The "[0]" represents a sometimes needed pad byte. (The regular expressions in this document are collected in Appendix A along with an explanation of notation.)

```
Chunk ::= ID #{ UBYTE* } [0]
```

One chunk output technique is to stream write a chunk header, stream write the chunk contents, then random access back to the header to fill in the size. Another technique is to make a preliminary pass over the data to compute the size, then write it out all at once.

# Strings, String Chunks, and String Properties

In a string of ASCII text, LF denotes a forced line break (paragraph or line terminator). Other control characters are not used. (Cf. Characters.)

The ckID for a chunk that contains a string of plain, unformatted text is "TEXT". As a practical matter, a text string should probably not be longer than 32767 bytes. The standard allows up to  $2^{31}$  - 1 bytes.

When used as a data property (see below), a text string chunk may be 0 to 255 characters long. Such a string is readily converted to a C string or a Pascal STRING [255]. The ckID of a property must be the property name, not "TEXT".

When used as a <u>part</u> of a chunk or data property, restricted C string format is normally used. That means 0 to 255 characters followed by a NUL byte (ASCII value 0).

# **Data Properties**

Data properties specify attributes for following (non-property) chunks. A data property essentially says

"identifier = value", for example "XY = (10, 200)", telling something about following chunks. Properties may only appear inside data sections ("FORM" chunks, cf. Data Sections) and property sections ("PROP" chunks, cf. Group PROP).

The form of a data property is a special case of Chunk. The ckID is a property name as well as a property type. The ckSize should be small since data properties are intended to be accumulated in RAM when reading a file. (256 bytes is a reasonable upper bound.) Syntactically:

Property ::= Chunk

When designing a data object, use properties to describe context information like the size of an image, even if they don't vary in your program. Other programs will need this information.

Think of property settings as assignments to variables in a programming language. Multiple assignments are redundant and local assignments temporarily override global assignments. The order of assignments doesn't matter as long as they precede the affected chunks. (Cf. LISTs, CATs, and Shared Properties.)

Each object type (FORM type) is a local name space for property IDs. Think of a "CMAP" property in a "FORM ILBM" as the qualified ID "ILBM.CMAP". Property IDs specified when an object type is designed (and therefore known to all clients) are called "standard" while specialized ones added later are "nonstandard".

# Links

Issue: A standard mechanism for "links" or "cross references" is very desirable for things like combining images and sounds into animations. Perhaps we'll define "link" chunks within FORMs that refer to other FORMs or to specific chunks within the same and other FORMs. This needs further work. EA IFF 1985 has no standard link mechanism.

For now, it may suffice to read a list of, say, musical instruments, and then just refer to them within a musical score by index number.

# File References

Issue: We may need a standard form for references to other files. A "file ref" would name a directory and a file in the same type of operating system as the ref's originator. Following the reference would expect the file to be on some mounted volume. In a network environment, a file ref could name a server, too.

Issue: What about a means to reference a portion of another file? Would this be a "file ref" plus a reference to a "link" within the target file?

# 4. Data Sections

The first thing we need of a file is to tell if it contains IFF data or not and, if so, does it contain the kind of data we're looking for? So we come to the notion of a "data section".

A "data section" or "data object" or IFF "FORM" is the main point of an IFF file. It is one high level object such as a picture or sound effect; self-contained and self-identifying. It could be a composite object like a musical score with nested musical instrument descriptions.

# **Group FORM**

A data section is a chunk with ckID "FORM" and this arrangement:

```
FORM ::= "FORM" #{ FormType (LocalChunk | FORM | LIST | CAT)* }
FormType ::= ID
LocalChunk ::= Property | Chunk
```

The ID "FORM" is a syntactic keyword like "struct" in C. Think of a "struct ILBM" containing a field "CMAP". If you see "FORM" you'll know to expect a FORM type ID (the structure name, "ILBM" in this example) and a particular contents arrangement or "syntax" (local chunks, FORMs, LISTs, and CATs). (LISTs and CATs are discussed in part 5, below.) A "FORM ILBM", in particular, might contain a local chunk "CMAP", an "ILBM.CMAP" (to use a qualified name).

So the chunk ID "FORM" indicates a data section. It implies that the chunk contains an ID and some number of nested chunks. In reading a FORM, like any other chunk, programs must respect its cksize as a virtual end-of-file for reading its contents, even if they're truncated.

The FormType (or FORM type) is a restricted ID that may not contain lower case letters or punctuation characters. (Cf. Type IDs. Cf. Single Purpose Files.)

The type-specific information in a FORM is composed of its "local chunks": data properties and other chunks. Each FORM type is a local name space for local chunk IDs. So "CMAP" local chunks in other FORM types may be unrelated to "ILBM.CMAP". More than that, each FORM type defines semantic scope. If you know what a FORM ILBM is, you'll know what an ILBM.CMAP is.

Local chunks defined when the FORM type is designed (and therefore known to all clients of this type) are called "standard" while specialized ones added later are "nonstandard".

Among the local chunks, property chunks give settings for various details like text font while the other chunks supply the essential information. This distinction is not clear cut. A property setting cancelled by a later setting of the same property has effect only on data chunks in between. E.g. in the sequence:

```
prop1 = x (propN = value) * prop1 = y
```

where the propNs are not prop1, the setting prop1 = x has no effect.

The following universal chunk IDs are reserved inside any FORM: "LIST", "FORM", "PROP", "CAT ", " ", "LIS1" through "LIS9", "FOR1" through "FOR9", and "CAT1" through "CAT9". (Cf. Chunks. Cf. Group LIST. Cf. Group PROP.) For clarity, these universal chunk names may not be FORM type IDs, either.

Part 5, below, talks about grouping FORMs into LISTs and CATs. They let you group a bunch of FORMs but don't impose any particular meaning or constraints on the grouping. Read on.

# Composite FORMs

A FORM chunk inside a FORM is a full-fledged data section. This means you can build a composite object like a multi-frame animation sequence from available picture FORMs and sound effect FORMs. You can insert additional chunks with information like frame rate and frame count.

Using composite FORMs, you leverage on existing programs that create and edit the component FORMs. Those editors <u>may</u> even look into your composite object to copy out its type of component, although it'll be the rare program that's fancy enough to do that. Such editors are <u>not</u> allowed to replace their component objects within your composite object. That's because the IFF standard lets you specify consistency requirements for the composite FORM such as maintaining a count or a directory of the components. Only programs that are written to uphold the rules of your FORM type should create or modify such FORMs.

Therefore, in designing a program that creates composite objects, you are <u>strongly requested</u> to provide a facility for your users to import and export the nested FORMs. Import and export could move the data through a clipboard or a file.

Here are several existing FORM types and rules for defining new ones.

### FTXT

An FTXT data section contains text with character formatting information like fonts and faces. It has no paragraph or document formatting information like margins and page headers. FORM FTXT is well matched to the text representation in Amiga's Intuition environment. See the supplemental document "FTXT" IFF Formatted Text.

# ILBM

"ILBM" is an InterLeaved BitMap image with color map; a machine-independent format for raster images. FORM ILBM is the standard image file format for the Commodore-Amiga computer and is useful in other environments, too. See the supplemental document "ILBM" IFF Interleaved Bitmap.

# **PICS**

The data chunk inside a "PICS" data section has ID "PICT" and holds a QuickDraw picture. Issue: Allow more than one PICT in a PICS? See <u>Inside Macintosh</u> chapter "QuickDraw" for details on PICTs and how to create and display them on the Macintosh computer.

The only standard property for PICS is "XY", an optional property that indicates the position of the PICT relative to "the big picture". The contents of an XY is a QuickDraw Point.

Note: PICT may be limited to Macintosh use, in which case there'll be another format for structured graphics in other environments.

# Other Macintosh Resource Types

Some other Macintosh resource types could be adopted for use within IFF files; perhaps MWRT, ICN, ICN#, and STR#.

Issue: Consider the candidates and reserve some more IDs.

# **Designing New Data Sections**

Supplemental documents will define additional object types. A supplement needs to specify the object's purpose, its FORM type ID, the IDs and formats of standard local chunks, and rules for generating and interpreting the data. It's a good idea to supply typedefs and an example source program that accesses the new object. See "ILBM" IFF Interleaved Bitmap for a good example.

Anyone can pick a new FORM type ID but should reserve it with Electronic Arts at their earliest convenience. [Issue: EA contact person? Hand this off to another organization?] While decentralized format definitions and extensions are possible in IFF, our preference is to get design consensus by committee, implement a program to read and write it, perhaps tune the format, and then publish the format with example code. Some organization should remain in charge of answering questions and coordinating extensions to the format.

If it becomes necessary to revise the design of some data section, its FORM type ID will serve as a version number (Cf. Type IDs). E.g. a revised "VDEO" data section could be called "VDE1". But try to get by with compatible revisions within the existing FORM type.

In a new FORM type, the rules for primitive data types and word-alignment (Cf. Primitive Data Types) may be overriden for the contents of its local chunks—but not for the chunk structure itself—if your documentation spells out the deviations. If machine-specific type variants are needed, e.g. to store vast numbers of integers in reverse bit order, then outline the conversion algorithm and indicate the variant inside each file, perhaps via different FORM types. Needless to say, variations should be minimized.

In designing a FORM type, encapsulate all the data that other programs will need to interpret your files. E.g. a raster graphics image should specify the image size even if your program always uses  $320 \times 200$  pixels x 3 bitplanes. Receiving programs are then empowered to append or clip the image rectangle, to add or drop bitplanes, etc. This enables a <u>lot</u> more compatibility.

Separate the central data (like musical notes) from more specialized information (like note beams) so simpler programs can extract the central parts during read-in. Leave room for expansion so other programs can squeeze in new kinds of information (like lyrics). And remember to keep the property chunks manageably short—let's say ≤ 256 bytes.

When designing a data object, try to strike a good tradeoff between a super-general format and a highly-specialized one. Fit the details to at least one particular need, for example a raster image might as well store pixels in the current machine's scan order. But add the kind of generality that makes it usable with foreseeable hardware and software. E.g. use a whole byte for each red, green, and blue color value even if this year's computer has only 4-bit video DACs. Think ahead and help other programs so long as the overhead is acceptable. E.g. run compress a raster by scan line rather than as a unit so future programs can swap images by scan line to and from secondary storage.

Try to design a general purpose "least common multiple" format that encompasses the needs of many programs without getting too complicated. Let's coalesce our uses around a few such formats widely separated in the vast design space. Two factors make this flexibility and simplicity practical. First, file storage space is getting very plentiful, so compaction is not a priority. Second, nearly any locally-performed data conversion work during file reading and writing will be cheap compared to the I/O time.

It must be ok to copy a LIST or FORM or CAT intact, e.g. to incorporate it into a composite FORM. So any kind of internal references within a FORM must be relative references. They could be relative to the start of the containing FORM, relative from the referencing chunk, or a sequence number into a collection.

With composite FORMs, you leverage on existing programs that create and edit the components. If you write a program that creates composite objects, <u>please</u> provide a facility for your users to import and export the nested FORMs. The import and export functions may move data through a separate file or a clipboard.

Finally, don't forget to specify all implied rules in detail.

# 5. LISTs, CATs, and Shared Properties

Data often needs to be grouped together like a list of icons. Sometimes a trick like arranging little images into a big raster works, but generally they'll need to be structured as a first class group. The objects "LIST" and "CAT" are IFF-universal mechanisms for this purpose.

Property settings sometimes need to be shared over a list of similar objects. E.g. a list of icons may share one color map. LIST provides a means called "PROP" to do this. One purpose of a LIST is to define the scope of a PROP. A "CAT", on the other hand, is simply a concatenation of objects.

Simpler programs may skip LISTs and PROPs altogether and just handle FORMs and CATs. All "fully-conforming" IFF programs also know about "CAT", "LIST", and "PROP". Any program that reads a FORM inside a LIST <u>must</u> process shared PROPs to correctly interpret that FORM.

# **Group CAT**

A CAT is just an untyped group of data objects.

Structurally, a CAT is a chunk with chunk ID "CAT" containing a "contents type" ID followed by the nested objects. The ckSize of each contained chunk is essentially a relative pointer to the next one.

```
CAT := "CAT " #{ ContentsType (FORM | LIST | CAT)* } \
ContentsType := ID
```

In reading a CAT, like any other chunk, programs must respect it's cksize as a virtual end-of-file for reading the nested objects even if they're malformed or truncated.

The "contents type" following the CAT's cksize indicates what kind of FORMs are inside. So a CAT of ILBMs would store "ILBM" there. It's just a hint. A CAT should have blank contents ID (" ") if it contains more than one kind of FORM.

CAT defines only the <u>format</u> of the group. The group's <u>meaning</u> is open to interpretation. This is like a list in LISP: the structure of cells is predefined but the meaning of the contents as, say, an association list depends on use. If you need a group with an enforced meaning (an "abstract data type" or Smalltalk "subclass"), some consistency constraints, or additional data chunks, use a composite FORM instead (Cf. Composite FORMs).

Since a CAT just means a concatenation of objects, CATs are rarely nested. Programs should really merge CATs rather than nest them.

# **Group LIST**

A LIST defines a group very much like CAT but it also gives a scope for PROPs (see below). And unlike CATs, LISTs should not be merged without understanding their contents.

Structurally, a LIST is a chunk with ckID "LIST" containing a "contents type" ID, optional shared properties, and the nested contents (FORMs, LISTs, and CATs), in that order. The ckSize of each contained chunk is a relative pointer to the next one. A LIST is not an arbitrary linked list—the cells are simply concatenated.

```
LIST := "LIST" #{ ContentsType PROP* (FORM | LIST | CAT)* }
ContentsType ::= ID
```

# **Group PROP**

PROP chunks may appear in LISTs (not in FORMs or CATs). They supply shared properties for the FORMs in that LIST. This ability to elevate some property settings to shared status for a list of forms is useful for both indirection and compaction. E.g. a list of images with the same size and colors can share one "size" property and one "color map" property. Individual FORMs can override the shared settings.

The contents of a PROP is like a FORM with no data chunks:

```
PROP ::= "PROP" #{ FormType Property* }
```

It means, "Here are the shared properties for FORM type <FormType>."

A LIST may have at most one PROP of a FORM type, and all the PROPs must appear before any of the FORMs or nested LISTs and CATs. You can have subsequences of FORMs sharing properties by making each subsequence a LIST.

Scoping: Think of property settings as variable bindings in nested blocks of a programming language. Where in C you could write:

An IFF file could contain:

```
LIST {
  PROP TEXT {
    FONT {TimesRoman}
                                      /* shared setting
                                                                      */
  FORM TEXT (
    FONT {Helvetica}
                                     /* local setting
                                                                      */
    CHRS {Hello }
                                      /* uses font Helvetica
                                                                      */
  FORM TEXT (
    CHRS {there.}
                                      /* uses font TimesRoman
                                                                      */
  }
```

The shared property assignments selectively override the reader's global defaults, but only for FORMs within the group. A FORM's own property assignments selectively override the global and group-supplied values. So when reading an IFF file, keep property settings on a stack. They're designed to be small

enough to hold in main memory.

Shared properties are semantically equivalent to copying those properties into each of the nested FORMs right after their FORM type IDs.

# **Properties for LIST**

Optional "properties for LIST" store the origin of the list's contents in a PROP chunk for the fake FORM type "LIST". They are the properties originating program "OPGM", processor family "OCPU", computer type "OCMP", computer serial number or network address "OSN ", and user name "UNAM". In our imperfect world, these could be called upon to distinguish between unintended variations of a data format or to work around bugs in particular originating/receiving program pairs. Issue: Specify the format of these properties.

A creation date could also be stored in a property but let's ask that file creating, editing, and transporting programs maintain the correct date in the local file system. Programs that move files between machine types are expected to copy across the creation dates.

# 6. Standard File Structure

### File Structure Overview

An IFF file is just a single chunk of type FORM, LIST, or CAT. Therefore an IFF file can be recognized by its first 4 bytes: "FORM", "LIST", or "CAT". Any file contents after the chunk's end are to be ignored.

Since an IFF file can be a group of objects, programs that read/write single objects can communicate to an extent with programs that read/write groups. You're encouraged to write programs that handle all the objects in a LIST or CAT. A graphics editor, for example, could process a list of pictures as a multiple page document, one page at a time.

Programs should enforce IFF's syntactic rules when reading and writing files. This ensures reliable data transfer. The public domain IFF reader/writer subroutine package does this for you. A utility program "IFFCheck" is available that scans an IFF file and checks it for conformance to IFF's syntactic rules. IFFCheck also prints an outline of the chunks in the file, showing the ckID and ckSize of each. This is quite handy when building IFF programs. Example programs are also available to show details of reading and writing IFF files.

A merge program "IFFJoin" will be available that logically appends IFF files into a single CAT group. It "unwraps" each input file that is a CAT so that the combined file isn't nested CATs.

If we need to revise the IFF standard, the three anchoring IDs will be used as "version numbers". That's why IDs "FOR1" through "FOR9", "LIS1" through "LIS9", and "CAT1" through "CAT9" are reserved.

IFF formats are designed for reasonable performance with floppy disks. We achieve considerable simplicity in the formats and programs by relying on the host file system rather than defining universal grouping structures like directories for LIST contents. On huge storage systems, IFF files could be leaf nodes in a file structure like a B-tree. Let's hope the host file system implements that for us!

Thre are two kinds of IFF files: single purpose files and scrap files. They differ in the interpretation of multiple data objects and in the file's external type.

# Single Purpose Files

A single purpose IFF file is for normal "document" and "archive" storage. This is in contrast with "scrap files" (see below) and temporary backing storage (non-interchange files).

The external file type (or filename extension, depending on the host file system) indicates the file's contents. It's generally the FORM type of the data contained, hence the restrictions on FORM type IDs.

Programmers and users may pick an "intended use" type as the filename extension to make it easy to filter for the relevant files in a filename requestor. This is actually a "subclass" or "subtype" that conveniently separates files of the same FORM type that have different uses. Programs cannot demand conformity to its expected subtypes without overly restricting data interchange since they cannot know about the subtypes to be used by future programs that users will want to exchange data with.

Issue: How to generate 3-letter MS-DOS extensions from 4-letter FORM type IDs?

Most single purpose files will be a single FORM (perhaps a composite FORM like a musical score containing nested FORMs like musical instrument descriptions). If it's a LIST or a CAT, programs should skip over unrecognized objects to read the recognized ones or the first recognized one. Then a program that can read a single purpose file can read something out of a "scrap file", too.

# Scrap Files

A "scrap file" is for maximum interconnectivity in getting data between programs; the core of a clipboard function. Scrap files may have type "IFF" or filename extension ".IFF".

A scrap file is typically a CAT containing alternate representations of the same basic information. Include as many alternatives as you can readily generate. This redundancy improves interconnectivity in situations where we can't make all programs read and write super-general formats. [Inside Macintosh chapter "Scrap Manager".] E.g. a graphically-annotated musical score might be supplemented by a stripped down 4-voice melody and by a text (the lyrics).

The originating program should write the alternate representations in order of "preference": most preferred (most comprehensive) type to least preferred (least comprehensive) type. A receiving program should either use the first appearing type that it understands or search for its own "preferred" type.

A scrap file should have at most <u>one</u> alternative of any type. (A LIST of same type objects is ok as one of the alternatives.) But don't count on this when reading; ignore extra sections of a type. Then a program that reads scrap files can read something out of single purpose files.

# Rules for Reader Programs

Here are some notes on building programs that read IFF files. If you use the standard IFF reader module "IFFR.C", many of these rules and details will be automatically handled. (See "Support Software" in Appendix A.) We recommend that you start from the example program "ShowILBM.C". You should also read up on recursive descent parsers. [See, for example, <u>Compiler Construction</u>, <u>An Advanced Course</u>.]

- The standard is very flexible so many programs can exchange data. This implies a program has to scan the file and react to what's actually there in whatever order it appears. An IFF reader program is a parser.
- For interchange to really work, programs must be willing to do some conversion during read-in. If the data isn't exactly what you expect, say, the raster is smaller than those created by your program, then adjust it. Similarly, your program could crop a large picture, add or drop bitplanes, and create/discard a mask plane. The program should give up gracefully on data that it can't convert.
- If it doesn't start with "FORM", "LIST", or "CAT", it's not an IFF-85 file.
- For any chunk you encounter, you must recognize its type ID to understand its contents.
- For any FORM chunk you encounter, you must recognize its FORM type ID to understand the contained "local chunks". Even if you don't recognize the FORM type, you can still scan it for nested FORMs, LISTs, and CATs of interest.
- Don't forget to skip the pad byte after every odd-length chunk.
- Chunk types LIST, FORM, PROP, and CAT are generic groups. They always contain a subtype ID followed by chunks.
- Readers ought to handle a CAT of FORMs in a file. You may treat the FORMs like document pages to sequence through or just use the first FORM.
- Simpler IFF readers completely skip LISTs. "Fully IFF-conforming" readers are those that handle LISTs, even if just to read the first FORM from a file. If you do look into a LIST, you must process shared

properties (in PROP chunks) properly. The idea is to get the correct data or none at all.

 The nicest readers are willing to look into unrecognized FORMs for nested FORM types that they do recognize. For example, a musical score may contain nested instrument descriptions and an animation file may contain still pictures.

Note to programmers: Processing PROP chunks is not simple! You'll need some background in interpreters with stack frames. If this is foreign to you, build programs that read/write only one FORM per file. For the more intrepid programmers, the next paragraph summarizes how to process LISTs and PROPs. See the general IFF reader module "IFFR.C" and the example program "ShowlLBM.C" for details.

Allocate a stack frame for every LIST and FORM you encounter and initialize it by copying the stack frame of the parent LIST or FORM. At the top level, you'll need a stack frame initialized to your program's global defaults. While reading each LIST or FORM, store all encountered properties into the current stack frame. In the example ShowILBM, each stack frame has a place for a bitmap header property ILBM.BMHD and a color map property ILBM.CMAP. When you finally get to the ILBM's BODY chunk, use the property settings accumulated in the current stack frame.

# **Rules for Writer Programs**

Here are some notes on building programs that write IFF files, which is much easier than reading them. If you use the standard IFF writer module "IFFW.C" (see "Support Software" in Appendix A), many of these rules and details will automatically be enforced. See the example program "Raw2ILBM.C".

- An IFF file is a single FORM, LIST, or CAT chunk.
- Any IFF-85 file must start with the 4 characters "FORM", "LIST", or "CAT", followed by a LONG cksize. There should be no data after the chunk end.
- Chunk types LIST, FORM, PROP, and CAT are generic. They always contain a subtype ID followed by chunks. These three IDs are universally reserved, as are "LIS1" through "LIS9", "FOR1" through "FOR9", "CAT1" through "CAT9", and " ".
- Don't forget to write a 0 pad byte after each odd-length chunk.
- Four techniques for writing an IFF group: (1) build the data in a file mapped into virtual memory, (2) build the data in memory blocks and use block I/O, (3) stream write the data piecemeal and (don't forget!) random access back to set the group length count, and (4) make a preliminary pass to compute the length count then stream write the data.
- Do not try to edit a file that you don't know how to create. Programs may look into a file and copy out nested FORMs of types that they recognize, but don't edit and replace the nested FORMs and don't add or remove them. That could make the containing structure inconsistent. You may write a new file containing items you copied (or copied and modified) from another IFF file, but don't copy structural parts you don't understand.
- You must adhere to the syntax descriptions in Appendex A. E.g. PROPs may only appear inside LISTs.

# Appendix A. Reference

# **Type Definitions**

The following C typedefs describe standard IFF structures. Declarations to use in practice will vary with the compiler. For example, 68000 Lattice C produces efficient comparison code if we define ID as an "unsigned long". A macro "MakeID" builds these IDs at compile time.

```
/* Standard IFF types. */
                                 /* 8 bits unsigned */
typedef unsigned char UBYTE;
                                 /* 16 bits signed */
typedef short WORD;
                                /* 16 bits unsigned */
typedef unsigned short UWORD;
                                /* 32 bits signed */
typedef long LONG;
typedef char ID[4];
typedef struct {
  ID
      ckID:
                                /* sizeof(ckData)
                                                     */
  LONG ckSize;
  UBYTE ckData[/* ckSize */];
  } Chunk;
/* ID typedef and builder for 68000 Lattice C. */
typedef LONG ID;
#define MakeID(a,b,c,d) ( (a)<<24 | (b)<<16 | (c)<<8 | (d) )
/* Globally reserved IDs. */
#define FORM MakeID('F','O','R','M')
#define LIST MakeID('L','I','S','T')
#define PROP MakeID('P','R','O','P')
#define CAT MakeID('C','A','T',' ')
#define FILLER MakeID(' ',' ',' ',' ')
```

# **Syntax Definitions**

Here's a collection of the syntax definitions in this document.

```
::= ID #{ UBYTE* } [0]
Chunk
            ::= Chunk
Property
            ::= "FORM" #{ FormType (LocalChunk | FORM | LIST | CAT) * }
FORM
           ::= ID
FormType
LocalChunk ::= Property | Chunk
            ::= "CAT " #{ ContentsType (FORM | LIST | CAT) * }
CAT
ContentsType ::= ID
            ::= "LIST" #{ ContentsType PROP* (FORM | LIST | CAT)* }
LIST
             ::= "PROP" #{ FormType Property* }
PROP
```

In this extended regular expression notation, the token "#" represents a cksize LONG count of the

following {braced} data bytes. Literal items are shown in "quotes", [square bracketed items] are optional, and "\*" means 0 or more instances. A sometimes-needed pad byte is shown as "[0]".

# **Defined Chunk IDs**

This is a table of currently defined chunk IDs. We'll also borrow some Macintosh IDs and data formats.

Group chunk IDs
FORM, LIST, PROP, CAT.
Future revision group chunk IDs
FOR1 ... FOR9, LIS1 ... LIS9, CAT1 ... CAT9.
FORM type IDs

(The above group chunk IDs may not be used for FORM type IDs.)
(Lower case letters and punctuation marks are forbidden in FORM type IDs.)

PLBM, ILBM, ANBM, FTXT, PICS, USCR, GSCR, UVOX, GVOX, SFX, FNTR, FNTV, VDEO, PDEF.

Data chunk IDs
" ", TEXT, PICT.

PROP LIST property IDs

OPGM, OCPU, OCMP, OSN, UNAM.

Formats for sampled sound, musical instrument, and musical score are currently being developed.

# **Support Software**

These public domain C source programs are available for use in building IFF-compatible programs:

IFF.H, IFFR.C, IFFW.C IFF reader and writer package. These modules handle many of

the details of reliably reading and writing IFF files.

IFFCheck.C This handy utility program scans an IFF file, checks that the

contents are well formed, and prints an outline of the chunks.

Packer.H, Packer.C, UnPacker.C Run encoder and decoder used for ILBM files.

ILBM.H, ILBMR.C, ILBMW.C Reader and writer support routines for raster image FORM ILBM.

ILBMR calls IFFR and UnPacker, ILBMW calls IFFW and Packer

ShowILBM.C Example caller of IFFR and ILBMR modules. This

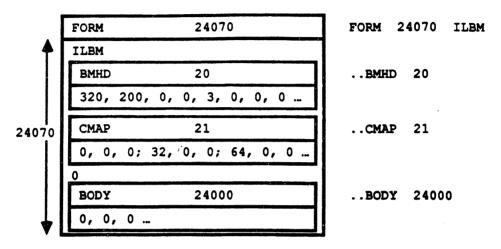

Commodore-Amiga program reads and displays a FORM ILBM.

Raw2ILBM.C Example ILBM writer program. As a demonstration, it reads a raw

raster image file and writes the image as a FORM ILBM file.

# **Example Diagrams**

Here's a box diagram for an example IFF file, a raster image FORM ILBM. This FORM contains a bitmap header property chunk BMHD, a color map property chunk CMAP, and a raster data chunk BODY. This particular raster is 320 x 200 pixels x 3 bit planes uncompressed. The "0" after the CMAP chunk represents a zero pad byte; included since the CMAP chunk has an odd length. The text to the right of the diagram shows the outline that would be printed by the IFFCheck utility program for this particular file.

This second diagram shows a LIST of two FORMs ILBM sharing a common BMHD property and a common CMAP property. Again, the text on the right is an outline a la IFFCheck.

| LIST 48114                  | LIST 48114 ILBM |
|-----------------------------|-----------------|
| ILBM                        |                 |
| PROP 62                     | PROP 62 ILBM    |
| ILBM                        |                 |
| BMHD 20                     | BMHD 20         |
| 320, 200, 0, 0, 3, 0, 0, 0  |                 |
| CMAP 21                     | CMAP 21         |
| 0, 0, 0; 32, 0, 0; 64, 0, 0 |                 |
| 0                           |                 |

# "ILBM" IFF Interleaved Bitmap

Date:

November 15, 1985

From:

Jerry Morrison, Electronic Arts

Status:

Released and in use

# 1. Introduction

"EA IFF 85" is Electronic Arts' standard for interchange format files. "ILBM" is the format for a 2 dimensional raster graphics image, specifically an InterLeaved bitplane BitMap image with color map. An ILBM is an IFF "data section" or "FORM type", which can be an IFF file or a part of one. (See the IFF reference.)

An ILBM is an archival representation designed for three uses. First, a standalone image that specifies exactly how to display itself (resolution, size, color map, etc.). Second, an image intended to be merged into a bigger picture which has its own depth, color map, and so on. And third, an empty image with a color map selection or "palette" for a paint program. ILBM is also intended as a building block for composite IFF FORMs like "animation sequence" and "structured graphics". Some uses of ILBM will be to preserve as much information as possible across disparate environments. Other uses will be to store data for a single program or highly cooperative programs while maintaining subtle details. So we're trying to accomplish a lot with this one format.

This memo is the IFF supplement for FORM ILBM. Section 2 defines the purpose and format of property chunks bitmap header "BMHD", color map "CMAP", hotspot "GRAB", destination merge data "DEST", sprite information "SPRT", and Commodore Amiga viewport mode "CAMG". Section 3 defines the standard data chunk "BODY". These are the "standard" chunks. Section 4 defines the nonstandard color range data chunk "CRNG". Additional specialized chunks like texture pattern can be added later. The ILBM syntax is summarized in Appendix A as a regular expression and in Appendix B as a box diagram. Appendix C explains the optional run encoding scheme. Appendix D names the committee responsible for this FORM ILBM standard.

Details of the raster layout are given in part 3, "Standard Data Chunk". Some elements are based on the Commodore Amiga hardware but generalized for use on other computers. An alternative to ILBM would be appropriate for computers with true color data in each pixel.

# 2. Standard Properties

The required property "BMHD" and any optional properties must appear before any "BODY" chunk. (Since an ILBM has only one BODY chunk, any following properties are superfluous.) Any of these properties may be shared over a LIST of FORMs IBLM by putting them in a PROP ILBM. (See the "EA IFF 85" memo.)

### **BMHD**

The required property "BMHD" holds a BitMapHeader as defined in these C declarations and following documentation. It describes the dimensions and encoding of the image, including data necessary to understand the BODY chunk to follow.

```
/* Choice of masking technique. */
typedef UBYTE Masking;
#define mskNone
#define mskHasMask
#define mskHasTransparentColor 2
#define mskLasso
typedef UBYTE Compression; /* Choice of compression algorithm applied to
  the rows of all source and mask planes. "cmpByteRun1" is the byte run
  encoding described in Appendix C. Do not compress across rows! */
                              0
#define cmpNone
                              1
#define cmpByteRun1
typedef struct {
                                                                         */
                               /* raster width & height in pixels
  UWORD w, h;
                                                                         */
                                /* pixel position for this image
  WORD x, y;
                                                                         */
                                /* # source bitplanes
  UBYTE nPlanes;
             masking;
  Masking
  Compression compression;
                                                                         */
                                /* unused; for consistency, put 0 here
  UBYTE pad1;
                                /* transparent "color number" (sort of)
                                                                         */
  UWORD transparentColor;
                                /* pixel aspect, a ratio width : height
                                                                         */
  UBYTE xAspect, yAspect;
                                                                         */
  WORD pageWidth, pageHeight; /* source "page" size in pixels
  } BitMapHeader;
```

Fields are filed in the order shown. The UBYTE fields are byte-packed.

The fields w and h indicate the size of the image rectangle in pixels. Each row of the image is stored in an integral number of 16 bit words. The number of words per row is Ceiling(w/16). The fields x and y indicate the desired position of this image within the destination picture. Some reader programs may ignore x and y. A safe default for writing an ILBM is (x, y) = (0, 0).

The number of source bitplanes in the BODY chunk (see below) is stored in nPlanes. An ILBM with a CMAP but no BODY and nPlanes = 0 is the recommended way to store a color map.

Note: Color numbers are color map index values formed by pixels in the destination bitmap, which may be deeper than nPlanes if a DEST chunk calls for merging the image into a deeper image.

The field masking indicates what kind of masking is to be used for this image. The value mskNone designates an opaque rectangular image. The value mskHasMask means that a mask plane is interleaved with the bitplanes in the BODY chunk (see below). The value mskHasTransparentColor indicates that pixels in the source planes matching transparentColor are to be considered "transparent". (Actually, transparentColor isn't a "color number" since it's matched with numbers formed by the source bitmap

rather than the possibly deeper destination bitmap. Note that having a transparent color implies ignoring one of the color registers. See CMAP, below.) The value mskLasso indicates the reader may construct a mask by lassoing the image as in MacPaint<sup>TM</sup>. To do this, put a 1 pixel border of transparentColor around the image rectangle. Then do a seed fill from this border. Filled pixels are to be transparent.

Issue: Include in an appendix an algorithm for converting a transparent color to a mask plane, and maybe a lasso algorithm.

A code indicating the kind of data compression used is stored in compression. Beware that using data compression makes your data unreadable by programs that don't implement the matching decompression algorithm. So we'll employ as few compression encodings as possible. The run encoding byteRun1 is documented in Appendix C, below.

The field pad1 is a pad byte and must be set to 0 for consistency. This field could get used in the future.

The transparentColor specifies which bit pattern means "transparent". This only applies if masking is mskHasTransparentColor or mskLasso (see above). Otherwise, transparentColor should be 0.

The pixel aspect ratio is stored as a ratio in the two fields xAspect and yAspect. This may be used by programs to compensate for different aspects or to help interpret the fields w, h, x, y, pageWidth, and pageHeight, which are in units of pixels. The fraction xAspect/yAspect represents a pixel's width/height. It's recommended that your programs store proper fractions in BitMapHeaders, but aspect ratios can always be correctly compared with the test

```
xAspect •yDesiredAspect = yAspect •xDesiredAspect
```

Typical values for aspect ratio are width: height = 10:11 (Amiga 320 x 200 display) and 1:1 (Macintosh™).

The size in pixels of the source "page" (any raster device) is stored in pageWidth and pageHeight, e.g. (320, 200) for a low resolution Amiga display. This information might be used to scale an image or to automatically set the display format to suit the image. (The image can be larger than the page.)

# **CMAP**

The optional (but encouraged) property "CMAP" stores color map data as triplets of red, green, and blue intensity values. The n color map entries ("color registers") are stored in the order 0 through n-1, totaling 3n bytes. Thus n is the ckSize/3. Normally, n would equal  $2^{nPlanes}$ .

A CMAP chunk contains a ColorMap array as defined below. (These typedefs assume a C compiler that implements packed arrays of 3-byte elements.)

The color components red, green, and blue represent fractional intensity values in the range 0 through 255 256ths. White is (255, 255, 255) and black is (0, 0, 0). If your machine has less color resolution, use the <u>high order</u> bits. Shift each field right on reading (or left on writing) and assign it to (from) a field in a local packed format like Color4, below. This achieves automatic conversion of images across environments with different color resolutions. On reading an ILBM, use defaults if the color map is absent or has fewer color registers than you need. Ignore any extra color registers.

The example type Color4 represents the format of a color register in working memory of an Amiga computer, which has 4 bit video DACs. (The ": 4" tells the C compiler to pack the field into 4 bits.)

Remember that every chunk must be padded to an even length, so a color map with an odd number of entries would be followed by a 0 byte, not included in the ckSize.

# GRAB

The optional property "GRAB" locates a "handle" or "hotspot" of the image relative to its upper left corner, e.g. when used as a mouse cursor or a "paint brush". A GRAB chunk contains a Point2D.

### DEST

The optional property "DEST" is a way to say how to scatter zero or more source bitplanes into a deeper destination image. Some readers may ignore DEST.

The contents of a DEST chunk is DestMerge structure:

The low order depth number of bits in planePick, planeOnOff, and planeMask correspond one-to-one with destination bitplanes. Bit 0 with bitplane 0, etc. (Any higher order bits should be ignored.) "1" bits in planePick mean "put the next source bitplane into this bitplane", so the number of "1" bits should equal nPlanes. "0" bits mean "put the corresponding bit from planeOnOff into this bitplane". Bits in planeMask gate writing to the destination bitplane: "1" bits mean "write to this bitplane" while "0" bits mean "leave this bitplane alone". The normal case (with no DEST property) is equivalent to planePick = planeMask =  $2^{nPlanes} - 1$ .

Remember that color numbers are formed by pixels in the destination bitmap (depth planes deep) not in the source bitmap (nPlanes planes deep).

## **SPRT**

The presence of an "SPRT" chunk indicates that this image is intended as a sprite. It's up to the reader program to actually make it a sprite, if even possible, and to use or overrule the sprite precedence data inside the SPRT chunk:

```
typedef UWORD SpritePrecedence; /* relative precedence, 0 is the highest */
```

Precedence 0 is the highest, denoting a sprite that is foremost.

Creating a sprite may imply other setup. E.g. a 2 plane Amiga sprite would have transparentColor = 0. Color registers 1, 2, and 3 in the CMAP would be stored into the correct hardware color registers for the hardware sprite number used, while CMAP color register 0 would be ignored.

# CAMG

A "CAMG" chunk is specifically for the Commodore Amiga computer. It stores a LONG "viewport mode". This lets you specify Amiga display modes like "dual playfield" and "hold and modify".

#### 3. Standard Data Chunk

#### Raster Layout

Raster scan proceeds left-to-right (increasing X) across scan lines, then top-to-bottom (increasing Y) down columns of scan lines. The coordinate system is in units of pixels, where (0,0) is the upper left comer.

The raster is typically organized as bitplanes in memory. The corresponding bits from each plane, taken together, make up an index into the color map which gives a color value for that pixel. The first bitplane, plane 0, is the low order bit of these color indexes.

A scan line is made of one "row" from each bitplane. A row is one planes' bits for one scan line, but padded out to a word (2 byte) boundary (not necessarily the first word boundary). Within each row, successive bytes are displayed in order and the most significant bit of each byte is displayed first.

A "mask" is an optional "plane" of data the same size (w, h) as a bitplane. It tells how to "cut out" part of the image when painting it onto another image. "One" bits in the mask mean "copy the corresponding pixel to the destination" while "zero" mask bits mean "leave this destination pixel alone". In other words, "zero" bits designate transparent pixels.

The rows of the different bitplanes and mask are <u>interleaved</u> in the file (see below). This localizes all the information pertinent to each scan line. It makes it much easier to transform the data while reading it to adjust the image size or depth. It also makes it possible to scroll a big image by swapping rows directly from the file without random-accessing to all the bitplanes.

#### BODY

The source raster is stored in a "BODY" chunk. This one chunk holds all bitplanes and the optional mask, interleaved by row.

The BitMapHeader, in a BMHD property chunk, specifies the raster's dimensions w, h, and nPlanes. It also holds the masking field which indicates if there is a mask plane and the compression field which indicates the compression algorithm used. This information is needed to interpret the BODY chunk, so the BMHD chunk must appear first. While reading an ILBM's BODY, a program may convert the image to another size by filling (with transparentColor) or clipping.

The BODY's content is a concatenation of scan lines. Each scan line is a concatenation of one row of data from each plane in order 0 through nPlanes-1 followed by one row from the mask (if masking = hasMask). If the BitMapHeader field compression is cmpNone, all h rows are exactly Ceiling(w/16) words wide. Otherwise, every row is compressed according to the specified algorithm and their stored widths depend on the data compression.

Reader programs that require fewer bitplanes than appear in a particular ILBM file can combine planes or drop the high-order (later) planes. Similarly, they may add bitplanes and/or discard the mask plane.

Do <u>not</u> compress across rows and don't forget to compress the mask just like the bitplanes. Remember to pad any BODY chunk that contains an odd number of bytes.

#### 4. Nonstandard Data Chunk

The following data chunk was defined after various programs began using FORM ILBM so it's a "nonstandard" chunk. That means there's some slight chance of name collisions.

#### **CRNG**

A "CRNG" chunk contains "color register range" information. It's useful for identifying a contiguous range of color registers for color cycling. There can be zero or more CRNG chunks in an ILBM, but all should appear before the BODY chunk.

The fields low and high indicate the range of color registers (color numbers) selected by this CRange.

The field active indicates whether color cycling is on or off. Zero means off.

The field rate determines the speed at which the colors will step when color cycling is on. The units are such that a rate of 60 steps per second is represented as  $2^{14} = 16384$ . Slower rates can be obtained by linear scaling; for 30 steps/second, rate = 8192; for 1 step/second, rate = 16384/60 = 273.

# Appendix A. ILBM Regular Expression

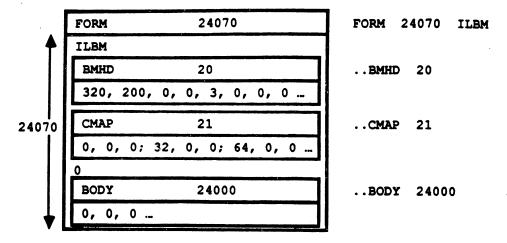

Here's a regular expression summary of the FORM ILBM syntax. This could be an IFF file or a part of one.

The token "#" represents a cksize LONG count of the following {braced} data bytes. E.g. a BMHD's "#" should equal sizeof (BitMapHeader). Literal strings are shown in "quotes", [square bracket items] are optional, and "\*" means 0 or more repetitions. A sometimes-needed pad byte is shown as "[0]".

The property chunks (BMHD, CMAP, GRAB, DEST, SPRT, and CAMG) and any CRNG data chunks may actually be in any order but all must appear before the BODY chunk since ILBM readers usually stop as soon as they read the BODY. If any of the 6 property chunks are missing, default values are "inherited" from any shared properties (if the ILBM appears inside an IFF LIST with PROPs) or from the reader program's defaults. If any property appears more than once, the last occurrence before the BODY is the one that counts since that's the one that modifies the BODY.

# Appendix B. ILBM Box Diagram

Here's a box diagram for a simple example: an uncompressed image  $320 \times 200$  pixels  $\times 3$  bitplanes. The text to the right of the diagram shows the outline that would be printed by the IFFCheck utility program for this particular file.

The "0" after the CMAP chunk is a pad byte.

# Appendix C. ByteRun1 Run Encoding

The run encoding scheme byteRun1 is best described by psuedo code for the decoder Unpacker (called UnPackBits in the Macintosh™ toolbox):

```
UnPacker:

LOOP until produced the desired number of bytes

Read the next source byte into n

SELECT n FROM

[0..127] => copy the next n+1 bytes literally

[-1..-127] => replicate the next byte -n+1 times

-128 => noop

ENDCASE;
ENDLOOP;
```

In the inverse routine Packer, it's best to encode a 2 byte repeat run as a replicate run except when preceded and followed by a literal run, in which case it's best to merge the three into one literal run. Always encode 3 byte repeats as replicate runs.

Remember that each row of each scan line of a raster is separately packed.

# **Appendix D. Standards Committee**

The following people contributed to the design of this FORM ILBM standard:

Bob "Kodlak" Burns, Commodore-Amiga R. J. Mical, Commodore-Amiga Jerry Morrison, Electronic Arts Greg Riker, Electronic Arts Steve Shaw, Electronic Arts Dan Silva, Electronic Arts Barry Walsh, Commodore-Amiga

# "FTXT" IFF Formatted Text

#### 1. Introduction

This memo is the IFF supplement for FORM FTXT. An FTXT is an IFF "data section" or "FORM type"—which can be an IFF file or a part of one—containing a stream of text plus optional formatting information."EA IFF 85" is Electronic Arts' standard for interchange format files. (See the IFF reference.)

An FTXT is an archival and interchange representation designed for three uses. The simplest use is for a "console device" or "glass teletype" (the minimal 2-D text layout means): a stream of "graphic" ("printable") characters plus positioning characters "space" ("SP") and line terminator ("LF"). This is not intended for cursor movements on a screen although it does not conflict with standard cursor-moving characters. The second use is text that has explicit formatting information (or "looks") such as font family and size, typeface, etc. The third use is as the lowest layer of a structured document that also has "inherited" styles to implicitly control character looks. For that use, FORMs FTXT would be embedded within a future document FORM type. The beauty of FTXT is that these three uses are interchangeable, that is, a program written for one purpose can read and write the others' files. So a word processor does not have to write a separate plain text file to communicate with other programs.

Text is stored in one or more "CHRS" chunks inside an FTXT. Each CHRS contains a stream of 8-bit text compatible with ISO and ANSI data interchange standards. FTXT uses just the central character set from the ISO/ANSI standards. (These two standards are henceforth called "ISO/ANSI" as in "see the ISO/ANSI reference".)

Since it's possible to extract just the text portions from future document FORM types, programs can exchange data without having to save both plain text and formatted text representations.

Character looks are stored as embedded control sequences within CHRS chunks. This document specifies which class of control sequences to use: the CSI group. This document does not yet specify their meanings, e.g. which one means "turn on Italic face". Consult ISO/ANSI.

Section 2 defines the chunk types character stream "CHRS" and font specifier "FONS". These are the "standard" chunks. Specialized chunks for private or future needs can be added later. Section 3 outlines an FTXT reader program that strips a document down to plain unformatted text. Appendix A is a code table for the 8-bit ISO/ANSI character set used here. Appendix B is an example FTXT shown as a box diagram. Appendix C is a racetrack diagram of the syntax of ISO/ANSI control sequences.

Amiga™ is a trademark of Commodore-Amiga, Inc.

Electronic Arts™ is a trademark of Electronic Arts.

IFF: "EA IFF 85" Standard for Interchange Format Files describes the underlying conventions for all IFF files.

ISO/ANSI: <u>ISO/DIS</u> 6429.2 and <u>ANSI</u> X3.64-1979. International Organization for Standardization (ISO) and American National Standards Institute (ANSI) data-interchange standards. The relevant parts of these two standards documents are identical. ISO standard 2022 is also relevant.

# 2. Standard Data and Property Chunks

The main contents of a FORM FTXT is in its character stream "CHRS" chunks. Formatting property chunks may also appear. The only formatting property yet defined is "FONS", a font specifier. A FORM FTXT with no CHRS represents an empty text stream. A FORM FTXT may contain nested IFF FORMs, LISTs, or CATs, although a "stripping" reader (see section 3) will ignore them.

#### **Character Set**

FORM FTXT uses the core of the 8-bit character set defined by the ISO/ANSI standards cited at the start of this document. (See Appendix A for a character code table.) This character set is divided into two "graphic" groups plus two "control" groups. Eight of the control characters begin ISO/ANSI standard control sequences. (See "Control Sequences", below.) Most control sequences and control characters are reserved for future use and for compatibility with ISO/ANSI. Current reader programs should skip them.

- C0 is the group of control characters in the range NUL (hex 0) through hex 1F. Of these, only LF (hex 0A) and ESC (hex 1B) are significant. ESC begins a control sequence. LF is the line terminator, meaning "go to the first horizontal position of the next line". All other C0 characters are not used. In particular, CR (hex 0D) is not recognized as a line terminator.
- G0 is the group of graphic characters in the range hex 20 through hex 7F. SP (hex 20) is the space character. DEL (hex 7F) is the delete character which is not used. The rest are the standard ASCII printable characters "!" (hex 21) through "~" (hex 7E).
- C1 is the group of extended control characters in the range hex 80 through hex 9F. Some of these
  begin control sequences. The control sequence starting with CSI (hex 9B) is used for FTXT
  formatting. All other control sequences and C1 control characters are unused.
- G1 is the group of extended graphic characters in the range NBSP (hex A0) through "y" (hex FF). It is one of the alternate graphic groups proposed for ISO/ANSI standardization.

#### **Control Sequences**

Eight of the control characters begin ISO/ANSI standard "control sequences" (or "escape sequences"). These sequences are described below and diagrammed in Appendix C.

```
G0 ::= (SP through DEL)
G1 ::= (NBSP through "Y")

ESC-Seq ::= ESC (SP through "/")* ("0" through "~")
ShiftToG2 ::= SS2 G0
ShiftToG3 ::= SS3 G0

CSI-Seq ::= CSI (SP through "?")* ("0" through "~")
DCS-Seq ::= (DCS | OSC | PM | APC) (SP through "~" | G1)* ST
```

"ESC-Seq" is the control sequence ESC (hex 1B), followed by zero or more characters in the range SP through "/" (hex 20 through hex 2F), followed by a character in the range "0" through "~" (hex 30 through hex 7E). These sequences are reserved for future use and should be skipped by current FTXT reader programs.

SS2 (hex 8E) and SS3 (hex 8F) shift the single following G0 character into yet-to-be-defined graphic sets G2 and G3, respectively. These sequences should not be used until the character sets G2 and G3 are standardized. A reader may simply skip the SS2 or SS3 (taking the following character as a corresponding G0 character) or replace the two-character sequence with a character like "?" to mean "absent".

FTXT uses "CSI-Seq" control sequences to store character formatting (font selection by number, type face, and text size) and perhaps layout information (position and rotation). "CSI-Seq" control sequences

start with CSI (the "control sequence introducer", hex 9B). Syntactically, the sequence includes zero or more characters in the range SP through "?" (hex 20 through hex 3F) and a concluding character in the range "@" through "~" (hex 40 through hex 7E). These sequences may be skipped by a minimal FTXT reader, i.e. one that ignores formatting information.

Note: A future FTXT standardization document will explain the uses of CSI-Seq sequences for setting character face (light weight vs. medium vs. bold, italic vs. upright, height, pitch, position, and rotation). For now, consult the ISO/ANSI references.

"DCS-Seq" is the control sequences starting with DCS (hex 90), OSC (hex 9D), PM (hex 9E), or APC (hex 9F), followed by zero or more characters each of which is in the range SP through "~" (hex 20 through hex 7E) or else a G1 character, and terminated by an ST (hex 9C). These sequences are reserved for future use and should be skipped by current FTXT reader programs.

#### **Data Chunk CHRS**

A CHRS chunk contains a sequence of 8-bit characters abiding by the ISO/ANSI standards cited at the start of this document. This includes the character set and control sequences as described above and summarized in Appendicies A and C.

A FORM FTXT may contain any number of CHRS chunks. Taken together, they represent a single stream of textual information. That is, the contents of CHRS chunks are effectively concatenated except that (1) each control sequence must be completely within a single CHRS chunk, and (2) any formatting property chunks appearing between two CHRS chunks affects the formatting of the latter chunk's text. Any formatting settings set by control sequences inside a CHRS carry over to the next CHRS in the same FORM FTXT. All formatting properties stop at the end of the FORM since IFF specifies that adjacent FORMs are independent of each other (although not independent of any properties inherited from an enclosing LIST or FORM).

#### **Property Chunk FONS**

The optional property "FONS" holds a FontSpecifier as defined in the C declaration below. It assignes a font to a numbered "font register" so it can be referenced by number within subsequent CHRS chunks. (This function is not provided within the ISO and ANSI standards.) The font specifier gives both a name and a description for the font so the recipient program can do font substitution.

By default, CHRS text uses font 1 until it selects another font. A minimal text reader always uses font 1. If font 1 hasn't been specified, the reader may use the local system font as font 1.

```
typedef struct {
  UBYTE id:
                 /* 0 through 9 is a font id number referenced by an SGR
                 control sequence selective parameter of 10 through 19.
                 Other values are reserved for future standardization.
                                                                         */
  UBYTE pad1;
                 /* reserved for future use; store 0 here
                                                                         */
  UBYTE proportional; /* proportional font? 0 = unknown, 1 = no, 2 = yes */
  UBYTE serif;
                      /* serif font? 0 = unknown, 1 = no, 2 = yes
                                                                         */
  char name[]; /* A NUL-terminated string naming the preferred font.
                                                                         */
  } FontSpecifier;
```

Fields are filed in the order shown. The UBYTE fields are byte-packed (2 per 16-bit word). The field pad1 is reserved for future standardization. Programs should store 0 there for now.

The field proportional indicates if the desired font is proportional width as opposed to fixed width. The

field serif indicates if the desired font is serif as opposed to sans serif. [Issue: Discuss font substitution!]

### **Future Properties**

New optional property chunks may be defined in the future to store additional formatting information. They will be used to represent formatting not encoded in standard ISO/ANSI control sequences and for "inherited" formatting in structured documents. Text orientation might be one example.

# **Positioning Units**

Unless otherwise specified, position and size units used in FTXT formatting properties and control sequences are in decipoints (720 decipoints/inch). This is ANSI/ISO Positioning Unit Mode (PUM) 2. While a metric standard might be nice, decipoints allow the existing U.S.A. typographic units to be encoded easily, e.g. "12 points" is "120 decipoints".

## 3. FTXT Stripper

An FTXT reader program can read the text and ignore all formatting and structural information in a document FORM that uses FORMs FTXT for the leaf nodes. This amounts to stripping a document down to a stream of plain text. It would do this by skipping over all chunks except FTXT.CHRS (CHRS chunks found inside a FORM FTXT) and within the FTXT.CHRS chunks skipping all control characters and control sequences. (Appendix C diagrams this text scanner.) It may also read FTXT.FONS chunks to find a description for font 1.

Here's a Pascal-ish program for an FTXT stripper. Given a FORM (a document of some kind), it scans for all FTXT.CHRS chunks. This would likely be applied to the first FORM in an IFF file.

```
PROCEDURE ReadFORM4CHRS();
                                {Read an IFF FORM for FTXT.CHRS chunks.}
   BEGIN
   IF the FORM's subtype = "FTXT"
     THEN ReadFTXT4CHRS()
     ELSE WHILE something left to read in the FORM DO BEGIN
          read the next chunk header:
          CASE the chunk's ID OF
             "LIST", "CAT ": ReadCAT4CHRS();
             "FORM": ReadFORM4CHRS();
             OTHERWISE skip the chunk's body;
             END
          END
  END:
{Read a LIST or CAT for all FTXT.CHRS chunks.}
PROCEDURE ReadCAT4CHRS();
  BEGIN
  WHILE something left to read in the LIST or CAT DO BEGIN
     read the next chunk header;
     CASE the chunk's ID OF
       "LIST", "CAT ": ReadCAT4CHRS();
       "FORM": ReadFORM4CHRS();
       "PROP": IF we're reading a LIST AND the PROP's subtype = "FTXT"
               THEN read the PROP for "FONS" chunks;
       OTHERWISE error--malformed IFF file;
       END
     END
  END;
PROCEDURE ReadFTXT4CHRS();
                            {Read a FORM FTXT for CHRS chunks.}
  BEGIN
  WHILE something left to read in the FORM FTXT DO BEGIN
     read the next chunk header;
     CASE the chunk's ID OF
       "CHRS": ReadCHRS():
       "FONS": BEGIN
          read the chunk's contents into a FontSpecifier variable;
          IF the font specifier's id = 1 THEN use this font:
       OTHERWISE skip the chunk's body;
       END
    END
  END:
```

```
{Read an FTXT.CHRS. Skip all control sequences and unused control chars.}
PROCEDURE ReadCHRS();
  BEGIN
  WHILE something left to read in the CHRS chunk DO
     CASE read the next character OF
       LF: start a new output line;
       ESC: SkipControl([' '..'/'], ['0'..'~']);
       IN [' '..'~'], IN [NBSP..'Y']: output the character;
                     {Just handle the following GO character directly.
       SS2, SS3: ;
                      ignoring the shift to G2 or G3.}
       CSI: SkipControl([' '..'?'], ['@'..'~']);
       DCS, OSC, PM, APC: SkipControl([' '..'~'] + [NBSP..'\pu'], [ST]);
       END
  END:
(Skip a control sequence of the format (rSet)* (tSet), i.e. any number of
  characters in the set rSet followed by a character in the set tSet.}
PROCEDURE SkipControl(rSet, tSet);
  VAR c: CHAR;
  BEGIN
  REPEAT c := read the next character
    UNTIL c NOT IN rSet;
  IF c NOT IN tSet
     THEN put character c back into the input stream;
  END
```

The following program is an optimized version of the above routines ReadFORM4CHRS and ReadCAT4CHRS for the case where you're ignoring fonts as well as formatting. It takes advantage of certain facts of the IFF format to read a document FORM and its nested FORMs, LISTs, and CATs without a stack. In other words, it's a hack that ignores all fonts and faces to cheaply get to the plain text of the document.

```
(Cheap scan of an IFF FORM for FTXT.CHRS chunks.)
PROCEDURE ScanFORM4CHRS();
  BEGIN
  IF the document FORM's subtype = "FTXT"
     THEN ReadFTXT4CHRS()
     ELSE WHILE something left to read in the FORM DO BEGIN
          read the next chunk header;
          IF it's a group chunk (LIST, FORM, PROP, or CAT)
             THEN read its subtype ID;
          CASE the chunk's ID OF
             "LIST", "CAT ":; {NOTE: See explanation below.*}
             "FORM": IF this FORM's subtype = "FTXT" THEN ReadFTXT4CHRS()
                                   {NOTE: See explanation below.*}
             OTHERWISE skip the chunk's body;
             END
          END
   END;
```

\*Note: This implementation is subtle. After reading a group header other than FORM FTXT it just continues reading. This amounts to reading all the chunks inside that group as if they weren't nested in a group.

# Appendix A: Character Code Table

This table corresponds to the ISO/DIS 6429.2 and ANSI X3.64-1979 8-bit character set standards. Only the core character set of those standards is used in FTXT.

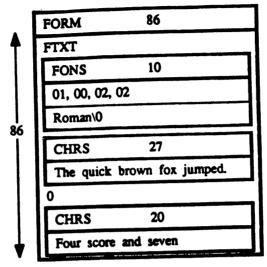

Two G1 characters aren't defined in the standards and are shown as dark gray entries in this table. Light gray shading denotes control characters. (DEL is a control character although it belongs to the graphic group G0.) The following five rare G1 characters are left blank in the table below due to limitations of available fonts: hex A8, D0, DE, F0, and FE.

ISO/DIS 6429.2 and ANSI X3.64-1979 Character Code LSN Most Significant Nibble (hex digit) 0 2 3 6 8 D E F 1 SP P DCS NBSP à 0 NUL 0 0 p Á 1 1 A Q Ñ á ñ ! a q 2 \*\* 2 2 Â Ò ¢ â В R b r Ò 3 Ā Ó 3 3 C S £ ã 6 C S X T 4 \$ 4 D d t ĝ ä ô Å 5 ٠, 5 E U e u ¥ μ å ō Æ 6 Ö £ 6 F V f v I ö æ 7 7 G W 5 w <del>く</del> を a Ç 8 8 H X h X Ø ( è Ø í É Ù 9 9 Y i 0 I У é ù ) Ê Ú A LF Z j ê : J ú Z Ë Û В ESC CSI + K k { **«** \* ë û C Ü < L ī ST 1/4 ì ü , Í D CR Ý M ] osc SHY 1/2 í m } ý E N SS2 PM ₿ 3/4 Î > n î F ? "SHY" is a "soft hyphen"

# Appendix B. FTXT Example

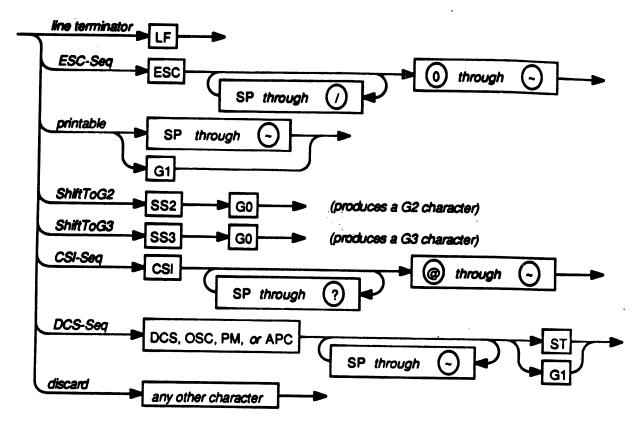

Here's a box diagram for a simple example: "The quick brown fox jumped. Four score and seven", written in a proportional serif font named "Roman".

The "0" after the first CHRS chunk is a pad byte.

# Appendix C. ISO/ANSI Control Sequences

This is a racetrack diagram of the ISO/ANSI characters and control sequences as used in FTXT CHRS chunks.

Of the various control sequences, only CSI-Seq is used for FTXT character formatting information. The others are reserved for future use and for compatibility with ISO/ANSI standards. Certain character sequences are syntactically malformed, e.g. CSI followed by a C0, C1, or G1 character. Writer programs should not generate reserved or malformed sequences and reader programs should skip them.

Consult the ISO/ANSI standards for the meaning of the CSI-Seq control sequences.

The two character set shifts SS2 and SS3 may be used when the graphic character groups G2 and G3 become standardized.

for future standardization.\*/

```

```
/* # bytes read/written of current chunk's data. */
```

Nov 14 17:45 1985 1ff.h Page 4

Computes the number of bytes not yet read from the current chunk, given ((gc)->ckHdr.ckSize - (gc)->bytasSoFar) 

# /\*\*\*\* Low Level IFF Chunk Reader \*\*\*\*\*/

/\* Given an open file, open a read context spanning the whole file.

† This is normally only called by ReadIFF.

† This sets new->clientFrame = clientFrame.

\* ASSUME context allocated by caller but not initialized

\* ASSUME caller doesn't deallocate the context before calling CloseRGroup. \* NOT\_IFF ERROR if the file is too short for even a chunk header. \*/ extern IFFP OpenRIFF (/\* BPTR, GroupContext \*, ClientFrame \* \*/);

clientFrame \*/ /\* file, new,

Open the remainder of the current chunk as a group read context.

\* This will be called just after the group's subtype ID has been read \* (automatically by GetChunkHdr for LIST, FORM, PROP, and CAI) so the

remainder is a sequence of chunks.

This sets new->clientFrame = parent->clientFrame. The caller should repoint it at a new clientframe if opening a LIST context so it'll have a "stack frame" to store PROPs for the LIST. (It's usually convenient to also

allocate a new Frame when you encounter FORM of the right type.)

ASSUME new context allocated by caller but not initialized

ASSUME caller doesn't deallocate the context or access the parent context before calling CloseRGroup.

BAD\_IFF ERROR if context end is odd or extends past parent. \*/ extern IFFP OpenRGroup(/\* GroupContext \*, GroupContext \* \*/);

\* after an error has occurred reading the group.

Skip any remaining bytes of the previous chunk and any padding, then read the next chunk header into context.cdddr.

Caller should dispatch on ckiD (and subtype) to an appropriate handler.

RETURNS context.cdddr.ckID (the ID of the new chunk header); END\_MARK if there are no more chunks in this context; or NOT\_IFF if the top level file chunk isn't a FORM, LIST, or CAT; or BAD\_IFF if malformed chunk, e.g. ckSize is negative or too big for containing context, ckID isn't positive,

See also GetfChunkdidr, GetflChunkdidr, and GetfChunkdidr, below.\*/

/\*\*\*\* IFF File Reader \*\*\*\*/

/\* This is a noop ClientProc that you can use for a getList, getForm, getProp, a or getCat procedure that just skips the group. A simple reader might just \* implement getForm, store &ReadICat in the getCat field of clientFrame, and \* use &SkipGroup for the getList and getProp procs.\*/
extern IFFP SkipGroup(/\* GroupContext \* \*/);

/\* IFF file reader

Given an open file, allocate a group context and use it to read the FCRM, LIST, or CAI and it's contents. The idea is to parse the file's contents, and for each FCRM, LIST, CAI, or PROP encountered, call the getForm,

getList, getCat, or getProp procedure in clientFrame, passing the GroupContext ptr.

This is achieved with the aid of ReadIList (which your getList should call) and ReadICat (which your getCat should call, if you don't just use GReadICat for your getCat). If you want to handle FORMs, LISTs, and CATs nested within FORMs, the getForm procedure must dispatch to getForm,

getList, and getCat (it can use CetFiChunkHdr to make this easy).

Normal return is IFF\_OKAY (if whole file scanned) or IFF\_DONE (if a client

getForm, getCat, and getProp procedures. \*/

This procedure assumes the image is in the Amiga's 320 \times 200 display mode.
Read an raw raster image file and write an IFF FORM ILBM file. 11/12/85.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             #define CkErr (expression) {if (ifferr = IFE_CKAY) ifferr = (expression);}

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         GKErr ( PutBMED (& formContext, & buildr) );
GKErr ( PutGMAP (& formContext, colorMap, depth) );
```

```
Nov 13 17:35 1985 raw2ilbm.c Page 2
```

3 11:03 1985 showilbm.c Page 1

```
CACRTY ( PutBODY (&formContext, bitmap, mask, &buildr, buffer, bufsize) );
                                                                     CdErr( EndNG-oup(&formContext) );
CdErr( CloseMG-oup(&fileContext) );
return( ifferr );
```

Put a picture into an IFF file.

{
 BYTE buffer[bufSize];
 return( PutAnILBM(file, bitmap, NUL,
 colorMap, bitmap->Depth, &millPoint,
 bufSize) );

utPicture(file, bitmap, colorMap) LONG file; struct BitMap \*bitmap;

IFFP PutPicture(file, bitmap, Point2D nullPoint = {0, 0};

That'll compile a program that skips all LISTs and PROPs in the input file. It will look in CATs for FORMs ILBM. That's suitable for most uses.

showilbm.c Page 3

set Fancy to 1. \*/

For a fancy version that handles LISTs and PROPs,

define Fancy 1

```
{ "(CLIENT_ERROR) ShowILBM bug or insufficient RAM."); { "(CLIENT_ERROR) ShowILBM bug or insufficient RAM."); { "(SHOL_CRUNK) A malformed FORM ILBM." }; { "(SHORT_CRUNK) A malformed FORM ILBM." }; { "(SAD_IFF) A mangled IFF file." };
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       ILEME rame
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            ILE Frame
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                /* ILEMErame is our "client frame" for reading FORMs ILEM in an IFF file.

* We allocate one of these on the stack for every LIST or FORM encountered

in the file and use it to hold BMED & CMAP properties. We also allocate

an initial one for the whole file.

* We allocate a new GroupContext (and initialize it by OpenRIFF or

* OpenRG-oup) for every group (FORM, CAI, LIST, or FROP) encountered. It's

* just a context for reading (mested) chunks.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               ILE Frame

## Appendix I

# Printer-Dependent Source Code

This appendix contains the printer-dependent source code for the following printers:

hpplus - Hewlett Packard LaserJet Plus

okimate20 - Okidata

epson - Epson X-80 series

diablo\_c - Diablo C-150

In addition, this appendix includes macros.i, which is required in order to assemble any of the ".asm" files.

These files are intended to aid developers in creating their own custom printer drivers that can be added to the DEVS: directory on an AmigaDOS disk. The documentation that explains the contents of these files is in the "Printer Device" chapter of the Amiga ROM Kernel manual.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           break;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      break:
                                                                                                                                                                                                                                                case 1 :
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      default:
```

### Types of Supported Printers

The available printers that are supported for the Amiga include both whole character (daisy wheel) and dot matrix (wire, ink jet, and laser) types. As with printer capabilities, printer prices range widely, from just over \$200 to over \$3500. In general, the dot matrix printers are capable of graphics output, while "whole character" printers are not.

Every attempt has been made to support a given feature on each printer that, itself, supports that feature. For example, the daisy wheel printers lack the capability to produce characters such as enlarged or italic print. Similarly, the dot matrix printers often lack such features as proportional spacing.

None of the supported printers currently supports all of the available features. (The Epson JX-80 and the HP LaserJet Plus come closest.) Whenever the system requests an unsupported feature, the PRT: handler simply ignores that request. (The "generic" printer driver currently ignores all feature requests.)

If two or more features are each available for a particular printer, they should be usable in combination. For example, Bold-Italic-Underscore is a possible style for many printers.

If your printer is not among those supported for the Amiga, you have two options. If your printer shares a number of common features with one of the supported printers, you can select that printer in Preferences. Keep in mind, however, that one or more of the chosen printer's features might not produce a similar effect on your printer.

Your second option is to select "Custom" from the list of supported printers in Preferences and "Generic" as the custom printer name. You can then construct a custom printer driver following the directions in the Amiga ROM Kernel Manual.

The following table lists the printers that are currently supported for the Amiga, grouped according to print technology.

### Table 1: Printers Supported on the Amiga

### Dot Matrix (Wire), Parallel

Manufacturer

Model

Commodore Epson

**CBM MPS 1000** Epson JX-80

Epson Epson MX-80, FX-80, ... Okimate

Okimate 20

### Daisy Wheel, Parallel

Manufacturer

Model

Alphacom Brother Diablo

Alphapro 101 HR-15XL

630 (Some models are serial)

Diablo Qume

Advantage D25 LetterPro 20

### Ink Jet, Parallel

Manufacturer

Model

Diablo

C-150

Laser, Serial

Manufacturer

Model

Hewlett Packard Hewlett Packard Laser Jet Laser Jet Plus

Other (Custom)

Manufacturer

Model

Limited support is offered for a "generic" printer.

# Table 2: Printer Functions Supported on the Amiga

### Legend:

ISO indicates that the sequence has been defined by the International Standards Organization. This is also very similar to ANSII x3.64.

DEC indicates a control sequence defined by Digital Equipment Corperation.

••• indicates a sequence unique to Amiga.

## Appendix J

### Software Memory Map

This appendix is for the convenience of the software developer who may be directly accessing the system hardware registers. It is simply the hardware memory map appropriate to the ROM Kernel manual.

A true software memory map, showing system utilization of the various sections of RAM and free space is not provided. The system is dynamically allocated and linked such that it would not be possible to show precisely which parts of RAM are utilized by the ROM Kernel. User code, if written with the Amiga Assembler or Amiga C, and linked by the Amiga linker is relocatable and can load and execute wherever there is a large enough area of memory in which it can fit.

Therefore, aside from specifying that Exec manages the lowest parts of the 68000 memory space (exception and trap vectors), no actual software memory utilization map can be provided.

SYSTEM MEMORY MAP -

This system memory map for the ROM Kernel manual is a combination of the Appendicies D (mem.map) and F (8520 info) from the Amiga PC Hardware Manual. Actual bit assignments for the 8520's and current additional details can be found in the Amiga Hardware Manual.

Note: If you select to read or write an address that is not specifically decoded, you WILL generate an address error.

ADDRESS RANGE NOTES

[ 256k RAM ]

000000-3FFFFF RAM space for 256k RAM

040000-080000 Not used if extra 256k board not installed.
Do NOT access in this range - dangerous side effects.

[ 512k RAM ]

000000-07FFFF RAM space for 512k RAM

080000-1FFFFF Do NOT access in this range.

200000-9FFFFF Expansion space (8 megabytes)

A00000-BEFFFF External decoder expansion space

BFD000-BFDF00 8520-B (accessed only at

Reserved for future use. See note (1) below.

EVEN byte addresses)

The underlined digit chooses which of the 16 internal registers of the 8520 is to be accessed. See also note (5)

ADDRESS RANGE NOTES

BFE001-BFEF01 8520-A (accessed only at

ODD byte addresses)

The underlined digit chooses which of the 16 internal registers of the 8520 is to be accessed.

Register Names are given in note (2) below.

Other addresses in the range of:

C00000-DFEFFF Reserved for future use

DFF000-DFFFFF Special purpose chips, where

the last three digits specify the chip register WORD address.

The chip addresses are specified in separate pages immediately following this overall memory

map.

E00000-E7FFFF Reserved for future use.

E80000-EFFFFF Expansion Slot decoding, see

note (1) below.

F00000-F7FFFF Reserved for future use.

F80000-FFFFFF SYSTEM ROM or kickstart RAM.

#### NOTES FOR THE SYSTEM MEMORY MAP:

#### (1) Expansion Slot decoding:

Boards designed to respond in this range must adhere to the auto-configuration guidelines to be published in Dec. 1985 by Commodore-Amiga Inc.

(2) The names of the registers within the 8520's are as follows. The address at which each are to be accessed (per note 1 above) is given here in this list.

#### Address for:

| 8520-A                                                                                                                                             | 8520-B                                                                                                                                   | NAME                                                                 | EXPLANATION                                                                                                                                                                                                                                                                                                                                             |

#### SPECIAL PURPOSE CHIP ADDRESSES

The following are the "offset" addresses for the special purpose chips in the Amiga PC. Each address figure shown below must be added to the base address of hex DFF000. Again the addressing follows the convention shown in note 1 of the system memory map.

Each register is located at an even WORD (16-bit) boundary.

| NAME    | OFFSET       | R/W | EXPLANATION                            |
|---------|--------------|-----|----------------------------------------|
|         |              |     |                                        |
| ADKCON  | 09E          | W   | Audio, Disk, Control write             |
| ADKCONR | 010          | R   | Audio, disk, Control read              |
|         |              |     |                                        |
| AUDODAT | 0AA          | W   | Audio channel 0 Data                   |
| AUD0LCH | 0 <b>A</b> 0 | W   | Audio channel 0 location (High 3 bits) |
| AUDOLCL | 0A2          | W   | Audio channel 0 location (Low 16 bits) |
| AUDOLEN | 0 <b>A4</b>  | W   | Audio Channel 0 length                 |
| AUD0PER | 0 <b>A</b> 6 | W   | Audio channel 0 Period                 |
| AUD0VOL | 0A8          | W   | Audio Channel O Volume                 |

| NAME               | OFFSET | R/W | EXPLANATION                                      |
|--------------------|--------|-----|--------------------------------------------------|
| AUD1DAT            | 0BA    | W   | Audio channel 1 Data                             |
| AUD1LCH            | 0B0    | W   | Audio channel 1 location (High 3 bits)           |

The following listing of the chip special purpose addresses is provided in numerical order by chip address for the convenience of software developers who may prefer this ordering sequence.

```
DMACONR
                    DMA control (and blitter status) read
           002
VHPOSR
           004 R
                    Read Vert and horiz Position of beam
VPOSR
           006 R
                    Read Vert most sig. bit (and frame flop)
DSKDATR
           008 ER
                    Disk DMA Data read (early read dummy address)
           00A R
JOY0DAT
                    Joystick-mouse 0 data (vert, horiz)
JOY1DAT
           00C
               R
                    Joystick-mouse 1 data (vert, horiz)
CLXDAT
           00E R
                    Collision data reg. (Read and clear)
ADKCONR
           010
                    Audio, disk, Control read
                    Pot counter data left pair (vert, horiz)
POTODAT
           012 R
POT1DAT
           014 R
                    Pot counter data right pair (vert, horiz)
POTINP
           016 R
                    Pot pin data read
SERDATR
           018 R
                    Serial Port Data and Status read
DSKBYTR
           01A R
                    Disk Data byte and status read
INTENAR
           01C R
                    Interrupt Enable bits Read
INTREOR
           01E R
                    Interrupt request bits (read)
DSKPTH
           020 W
                    Disk pointer (High 3 bits)
DSKPTL
           022 W
                    Disk pointer (Low 16 bits)
DSKLEN
           024 W
                    Disk length
DSKDAT
           026 W
                    Disk DMA Data write
REFPTR
           028 W
                    Refresh pointer
VHPOSW
           02A W
                    Write Vert and horiz Position of beam
VPOSW
           02C W
                    Write Vert most sig. bit (and frame flop)
SERDAT
           030 W
                    Serial Port Data and stop bits write
SERPER
           032 W
                    Serial Port Period and control
POTGO
           034 W
                    Pot Port (4 bit) Direction and Data,
           038 S
                    Strobe for horiz sync with VB and EQU
STREQU
STRVBL
           03A S
                    Strobe for horiz sync with VB (Vert. Blank)
STRHOR
           03C S
                    Strobe for horiz sync
STRLONG
                    Strobe for ident. of long horzontal line.
           03E S
BLTCONO
           040 W
                    Blitter control register 0
BLTCON1
           042 W
                    Blitter control register 1

## Appendix K

# Skeleton Device, Skeleton Library

This appendix contains source code for a skeleton device and a skeleton library. You can use this code to create your own custom devices and libraries to add to the Amiga.

# Appendix L

# **Disk Format Information**

This appendix contains information useful to the developer who desires to take over the entire machine. That is, rather than use AmigaDOS to load the code, the application is to boot directly after Kickstart, not using AmigaDOS or Intuition. This appendix provides two pieces of information: the disk boot block format, and the format of the actual data on disk.

#### THE BOOT PROCESS

The first two sectors are read into the system at an arbitrary position; therefore, the code MUST be PC-relative. The first three longwords are as in devices/bootblock.h. The type should be BBID\_DOS; the checksum must be correct (as in additive carry wraparound sum of 0xffffffff). Execution starts at location 12 of the sectors that were read in.

The code is called with an open disk I/O request in Al (see the TrackDisk chapter for the format of this IORequest block). The boot code is free to use it as it wishes (it may trash Al, but must not trash the io block itself).

The boot code returns two values: D0 and A0. D0 is a failure code -- if it is non-zero then a system alert will be called, then the boot code falls into the debugger.

If D0 is null then A0 contains the start address to jump to. The strap module will free the boot sectors, close the I/O block, do any other cleanup that is required, and jump to the location pointed to by A0.

#### COMMODORE-AMIGA DISK FORMAT

The following are details about how the bits on the Commodore-Amiga disk are actually written.

Gross Data Organization:

3 1/2 inch disk double-sided 80 cylinders/160 tracks

## Per-track Organization:

Nulls written as a gap, then 11 sectors of data. No gaps written between sectors.

#### Per-sector Organization:

All data is MFM encoded. This is the pre-encoded contents of each sector:

[above 4 bytes treated as one longword for purposes of MFM encoding]

16 bytes of OS recovery info (NOTE 2)

[treated as a block of 16 bytes for encoding]
four bytes of header checksum

[treated as a longword for encoding]
four bytes of data-area checksum

[treated as a longword for encoding]
512 bytes of data

[treated as a block of 512 bytes for encoding]

#### NOTES:

#### NOTE 1.

The track number and sector number are constant for each particular sector. However, the sector offset byte changes each time we rewrite the track.

The Amiga does a full track read starting at a random position on the track and going for slightly more than a full track read to assure that all data gets into the buffer. The data buffer is examined to determine where the first sector of data begins as compared to the start of the buffer. The track data is block moved to the beginning of the buffer so as to align some sector with the first location in the buffer.

Because we start reading at a random spot, the read data may be divided into three chunks: a series of sectors, the track gap, and another series of sectors. The sector offset value tells the disk software how many more sectors remain before the gap. From this the software can figure out the buffer memory location of the last byte of legal data in the buffer. It can then search past the gap for the next sync byte and, having found it, can block move the rest of the disk data so that all 11 sectors of data are contiguous.

#### Example:

first-ever write of the track from a buffer like this:

<GAP> |sector0|sector1|sector2|....|sector10|

sector offset values:

11 10 9 .... 1

(if I find this one at the start of my read buffer, then I know there are this many more sectors with no intervening gaps before I hit a gap).

sample read of this track:

<junk>|sector9|sector10|<gap>|sector0|...|sector8|<junk>

value of 'sectors till end of write':

 $2 \qquad 1 \qquad \dots \qquad 11 \qquad \qquad 3$ 

result of track realligning:

<GAP>|sector9|sector10|sector0|...|sector8|

new sectors till end of write:

11 10 9 ... 1

so that when the track is rewritten, the sector offsets are adjusted to match the way the data was written.

NOTE 2. This is operating systems dependent data and relates to how AmigaDos assigns sectors to files.

Reserved for future use.

#### **GENERAL:**

When data is MFM encoded, the encoding is performed on the basis of a data block-size. In the sector encoding described above, there are bytes individually encoded; three segments of 4 bytes of data each, treated as longwords; one segment of 16 bytes treated as a block; two segments of longwords for the header and data checksums; and the data area of 512 bytes treated as a block.

When the data is encoded, the odd bits are encoded first, then the even bits of the block.

(Make a block of bytes formed from all odd bits of the block, encode as MFM.

Make a block of bytes formed from all even bits of the block, encode as MFM. Even bits are shifted left one bit position before being encoded.)

```
SOURCE CODE FOR DATA ENCODE/DECODE
```

```
decodeBlock( mfmbuffer, userbuffer, numwords )
                        /* the encoded data */
WORD *mfmbuffer;
                        /* where to put the decoded data */
WORD *userbuffer;
                        /* the number of WORDS of data (not bytes) */
int numwords;
    WORD *oddptr, *evenptr, oddbits, evenbits;
    oddptr = mfmbuffer;
    /* the even region starts right after the odd one */
    evenptr = &mfmbuffer[numwords];
    while( numwords-- > 0 ) {
        /* mask off the mfm clock bits, and shift the word */
        oddbits = ((*oddptr++ << 1) & 0xAAAA);
        /* even bits are already in the right place. Just mask off clock */
        evenbits = ((*evenptr++) \& 0x5555);
        /* recombine the two sections */
        *userbuffer++ = oddbits | evenbits;
    }
}
encodeBlock( mfmbuffer, userbuffer, numwords )
WORD *mfmbuffer;
                        /* where to put the encoded data */
                        /* the user data, before encoding */
WORD *userbuffer;
int numwords;
                        /* the number of WORDS of data (not bytes) */
    WORD *oddptr, *evenptr;
    WORD *ubuf;
    oddptr = mfmbuffer;
    /* the even region starts right after the odd one */
    evenptr = &mfmbuffer[numwords];
    /* mfmencode takes one word of mfm data can correctly sets
     * the clock bits
    /* encode the odd bits */
    for( ubuf = userbuffer, i = numwords; i > 0; i-- ) {
        oddptr++ = mfmencode( (*ubuf++ >> 1) & 0x5555);
    }
    /* encode the even bits */
    for( ubuf = userbuffer, i = numwords; i > 0; i-- ) {
        evenptr++ = mfmencode( *ubuf++ & 0x5555 );
    }
}
